

LARGE DEVIATIONS FOR POINT PROCESSES BASED ON STATIONARY SEQUENCES WITH HEAVY TAILS

HENRIK HULT AND GENNADY SAMORODNITSKY[†]

ABSTRACT. In this paper we propose a framework that enables the study of large deviations for point processes based on stationary sequences with regularly varying tails. This framework allows us to keep track not of the magnitude of the extreme values of a process, but also of the order in which these extreme values appear. Particular emphasis is put on (infinite) linear processes with random coefficients. The proposed framework provide a rather complete description of the joint asymptotic behavior of the large values of the stationary sequence. We apply the general result on large deviations for point processes to derive the asymptotic decay of partial sum processes as well as ruin probabilities.

1. INTRODUCTION

In some applications, including network traffic and finance, time series are encountered where the marginal distributions are heavy-tailed and clustering of extreme values is observed. More precisely, the marginal distributions have a power-like decay and large values tend to occur at nearby points in time, forming clusters. When studying the probability of rare events it is usually important not only to determine the size and frequency of clusters of extreme values but also to capture the internal structure of the clusters. Unfortunately, in many “standard” limiting theorems dealing with heavy tailed processes the fine structure of a cluster is lost in the limit, including the ordering of the points in a cluster. This point is discussed in some detail in Section 3 below. To overcome this problem, we propose a new framework for investigating large deviations for stochastic processes with heavy tails. Specifically, large deviations are studied at the level of point processes associated to the underlying stochastic process. In this way it is possible to preserve the fine structure of the clusters of large values for a fairly general class of multivariate time series.

The processes studied here is the class of random coefficient linear processes. It consists of d -dimensional time series $(X_k)_{k \in \mathbf{Z}}$ with the stochastic representation

$$X_k = \sum_{j \in \mathbf{Z}} A_{k,j} Z_{k-j}. \quad (1.1)$$

Key words and phrases. Stationary sequence, regular variation, large deviations, point process.

[†] Hult’s research was partially supported by the Swedish Research Council. Samorodnitsky’s research was partially supported by NSA grant H98230-06-1-0069 and ARO grant W911NF-07-1-0078 at Cornell University.

The sequence $(Z_j)_{j \in \mathbf{Z}}$ consists of independent and identically distributed random vectors with values in $\mathbf{R}^p$. A generic element of this sequence is denoted by Z . Each $A_{k,j}$ is a random $(d \times p)$ matrix. It is assumed that the sequence $(\mathbb{A}_k)_{k \in \mathbf{Z}}$ is stationary and each $\mathbb{A}_k$ is itself a sequence of matrices, $\mathbb{A}_k = (A_{k,j})_{j \in \mathbf{Z}}$. It is assumed that the sequence $(\mathbb{A}_k)_{k \in \mathbf{Z}}$ is independent of the sequence $(Z_k)_{k \in \mathbf{Z}}$.

The probability of large values of the process (X_k) depends, of course, on the distributional assumptions on Z and $A_{k,j}$. In this paper the heavy-tailed case is considered; the distribution of Z is assumed to be regularly varying. Certain moment conditions will also be imposed on the random matrices $A_{k,j}$ (see Section 2).

Probability distributions with regularly varying tails have become important building blocks in a wide variety of stochastic models. Evidence for power-tail distributions is well documented in a large number of applications including computer networks, telecommunications, finance, insurance, hydrology, atmospheric sciences, geology, ecology etc. For the multi-dimensional version of (1.1) the notion of multivariate regular variation will be used.

A d -dimensional random vector Z has a regularly varying distribution if there exists a non-null Radon measure μ on $\mathbf{R}^d \setminus \{0\}$ such that

$$\frac{P(u^{-1}Z \in \cdot)}{P(|Z| > u)} \rightarrow \mu(\cdot) \quad (1.2)$$

in $\mathbf{M}_0(\mathbf{R}^d)$. Here $\mathbf{M}_0(\mathbf{R}^d)$ denotes the space of Radon measures on $\mathbf{R}^d$ whose restriction to $\{|x| \geq r\}$ is finite for each $r > 0$, with $|\cdot|$ denoting the Euclidean norm. Convergence $m_n \rightarrow m$ in $\mathbf{M}_0(\mathbf{R}^d)$ is defined as the convergence $m_n(f) \rightarrow m(f)$ for each bounded continuous function f vanishing on some neighborhood of the origin. See Hult and Lindskog (2006) for more details on the space $\mathbf{M}_0(\mathbf{R}^d)$.

The limiting measure μ necessarily obeys a homogeneity property: there is an $\alpha > 0$ such that $\mu(uB) = u^{-\alpha}\mu(B)$ for all Borel sets $B \subset \mathbf{R}^d \setminus \{0\}$. This follows from standard regular variation arguments (see e.g. Hult and Lindskog (2006), Theorem 3.1). The notation $Z \in \text{RV}(\mu, \alpha)$ will be used for a random vector satisfying (1.2). See Basrak (2000), Resnick (1987, 2006), and Hult and Lindskog (2006) for more on multivariate regular variation.

The class of stochastic models with representation (1.1) is quite flexible and contains a wide range of useful time series. Here are some examples.

Example 1.1 (Linear process). Let (A_j) be a sequence of deterministic real-valued $d \times p$ -matrices. Then, assuming convergence, $X_k = \sum_{j \in \mathbf{Z}} A_j Z_{k-j}$ is a linear process. It is, clearly, stationary. The (d -dimensional) marginal distribution of this process has the representation (1.1).

Example 1.2 (SRE). An important particular case of the random coefficient linear process is the stationary solution of a stochastic recurrence equation (SRE).

Assume that $p = d$, and let $(Y_k, Z_k)_{k \in \mathbf{Z}}$ be a sequence of independent and identically distributed pairs of $d \times d$ -matrices and d -dimensional random vectors. Put

$$\Pi_{n,m} = \begin{cases} Y_n \cdots Y_m, & n \leq m, \\ \text{Id}, & n > m, \end{cases}$$

where Id is the $d \times d$ identity matrix. Under certain assumptions assuring existence of a stationary solution of a stochastic recurrence equation (SRE)

$$X_k = Y_k X_{k-1} + Z_k, \quad k \in \mathbf{Z}, \quad (1.3)$$

this stationary solution can be represented by a random coefficient linear process with $A_{k,j} = \Pi_{k-j+1,k}$, $j \geq 0$, and $A_{k,j} = 0$, $j < 0$; (e.g Kesten, 1973). Then the marginal distribution of the stationary solution to the SRE is of the form (1.1).

Example 1.3 (Stochastic volatility). Let (X_k) be the solution of the SRE in the previous example where we assume $X_k \in (0, \infty)^d$ a.s. Let (V_k) be a sequence of independent and identically distributed random diagonal matrices independent of (X_k) . Then $U_k = V_k X_k$ has representation

$$U_k = \sum_{j \in \mathbf{Z}} \tilde{A}_{k,j} Z_{k-j},$$

where $\tilde{A}_{k,j} = V_k A_{k,j}$ and $A_{k,j}$ as in the previous example. The sequence U_k can be interpreted as a stochastic volatility model where X_k is the volatility.

2. CONVERGENCE AND TAIL BEHAVIOR

Consider a time series (X_k) with stochastic representation (1.1). Throughout this paper it is assumed that

$$\left. \begin{array}{l} Z \in \text{RV}(\mu, \alpha) \text{ and} \\ \text{if } \alpha > 1, \text{ we assume additionally that } EZ = 0. \end{array} \right\} \quad (2.1)$$

To begin the study of extreme values for the time series (1.1) a first requirement is to establish conditions under which the infinite series converge a.s. and determine the tail behavior of the distribution of X_k . Under certain conditions results on the tail behavior were obtained recently by Hult and Samorodnitsky (2008), under a “predictability” assumption on the matrices $(A_{k,j})$. Here we summarize the results and remind the reader that in the current paper it is assumed that $(A_{k,j})$ and (Z_j) are independent. Theorem 2.1 below describes the marginal tails; for simplicity we drop the time subscript k from both X_k and $A_{k,j}$.

Throughout the paper the notation $\|A\|$ is used for the operator norm of a matrix A . The summation index will be omitted when it is clear what it is.

Theorem 2.1. *Suppose that (2.1) holds and there is $0 < \varepsilon < \alpha$ such that*

$$\sum E \|A_j\|^{\alpha-\varepsilon} < \infty \quad \text{and} \quad \sum E \|A_j\|^{\alpha+\varepsilon} < \infty, \quad \alpha \in (0, 1) \cup (1, 2), \quad (2.2)$$

$$E \left(\sum \|A_j\|^{\alpha-\varepsilon} \right)^{\frac{\alpha+\varepsilon}{\alpha-\varepsilon}} < \infty, \quad \alpha \in \{1, 2\}, \quad (2.3)$$

$$E \left(\sum \|A_j\|^2 \right)^{\frac{\alpha+\varepsilon}{2}} < \infty, \quad \alpha \in (2, \infty). \quad (2.4)$$

Then the series (1.1) converges a.s. and

$$\frac{P(u^{-1}X \in \cdot)}{P(|Z| > u)} \rightarrow E \left[\sum \mu \circ A_j^{-1}(\cdot) \right], \quad (2.5)$$

in $\mathbf{M}_0(\mathbf{R}^d)$.

The right hand side of (2.5) is interpreted as

$$E\left[\sum \mu \circ A_j^{-1}(B)\right] = E\left[\sum \mu\{z : A_j z \in B\}\right],$$

for any Borel set $B \subset \mathbf{R}^d$. When both Z and $A_{k,j}$ are univariate ($d = p = 1$), the limiting measure μ of Z has the representation

$$\mu(dz) = (w \alpha z^{-\alpha-1} I\{z > 0\} + (1-w) \alpha (-z)^{-\alpha-1} I\{z < 0\}) dz \quad (2.6)$$

for some $w \in [0, 1]$. Then (2.5) becomes

$$\frac{P(X > ux)}{P(|Z| > u)} \rightarrow \sum E\left[|A_j|^\alpha (w I\{A_j > 0\} + (1-w) I\{A_j < 0\})\right] x^{-\alpha},$$

for each $x > 0$, with a similar expression for the negative tail.

Example 2.1 (Linear process). If (X_k) is a linear process ($A_{k,j} = A_j$ deterministic) and $d = p = 1$, then

$$\frac{P(X > ux)}{P(|Z| > u)} \rightarrow \sum \left[|A_j|^\alpha (w I\{A_j > 0\} + (1-w) I\{A_j < 0\})\right] x^{-\alpha}.$$

Example 2.2 (SRE). Suppose (X_k) is the solution to the stochastic recurrence equation in Example 1.2 with Y satisfying $E\|Y\|^{\alpha+\varepsilon} < 1$ for some $\varepsilon > 0$. Then, in the case $d = p = 1$,

$$\frac{P(X > ux)}{P(|Z| > u)} \rightarrow \frac{w(1 - E(Y^+)^\alpha) + (1-w)E(Y^-)^\alpha}{(1 - E(Y^+)^\alpha)^2 + (E(Y^-)^\alpha)^2} x^{-\alpha},$$

see Hult and Samorodnitsky (2008), Example 3.3. Here, and throughout, $x^+ = \max\{x, 0\}$ denotes the positive part of x , and $x^- = \max\{-x, 0\}$ its negative part. In particular, if Y is nonnegative then $w = 1$, $EY^- = 0$, and the expression in the last display reduces to

$$\frac{P(X > ux)}{P(|Z| > u)} \rightarrow (1 - EY^\alpha)^{-1} x^{-\alpha}.$$

Example 2.3 (Stochastic volatility). Let (X_k) be as in the previous example where $d = p = 1$ and Y and Z are nonnegative. Let (V_k) be a sequence of independent and identically distributed random variables, independent of (X_k) . Suppose $EV^{\alpha+\varepsilon} < \infty$ for some $\varepsilon > 0$. Then $U_k = V_k X_k$ satisfies

$$\frac{P(U > ux)}{P(Z > u)} \rightarrow \frac{EV^\alpha}{1 - EY^\alpha} x^{-\alpha},$$

Remark 2.1. The following two observations will be useful for later reference. It follows from Remark 4.1 in Hult and Samorodnitsky (2008) that for any increasing truncation $n(x) \uparrow \infty$ one has

$$\lim_{x \rightarrow \infty} \frac{P(|\sum_{|j| > n(x)} A_j Z_j| > x)}{P(|Z| > x)} = 0. \quad (2.7)$$

Further, only values of Z_j comparable to the level x matter in the sense that

$$\lim_{\tau \rightarrow 0} \limsup_{x \rightarrow \infty} \frac{P(|\sum_{j \in \mathbb{Z}} A_j Z_j I\{|Z_j| \leq \tau x\}| > x)}{P(|Z| > x)} = 0. \quad (2.8)$$

3. WHY ARE THE LARGE DEVIATIONS OF POINT PROCESSES NEEDED?

In this section we discuss, somewhat informally, the joint asymptotic behavior of large values of the sequence (X_k) in (1.1). The goal is to set up the necessary background and intuition for the general result in Section 4. We consider two special cases, that of sequences of independent and identically distributed random variables as well as of moving average processes.

3.1. Independent and identically distributed random variables. Consider a sequence (Z_k) of independent and identically distributed real-valued random variables with $Z \in \text{RV}(\alpha, \mu)$ and μ as in (2.6). As mentioned before, for $\alpha > 1$ it is assumed that $EZ_k = 0$. It is well known that for each $n \geq 1$ the vector $(Z_1, \dots, Z_n)$ is regularly varying with limit measure $\mu^{(n)}$ concentrated on the coordinate axes;

$$\mu^{(n)}(dz_1, \dots, dz_n) = \sum_{i=1}^n \mu(dz_i) \prod_{j \neq i} \delta_0(dz_j),$$

where δ_x is a unit mass at x . The interpretation is that, asymptotically, only one of the variables $Z_1, \dots, Z_n$ will have large absolute value and each variable is equally likely of being large.

The same intuition holds true when considering variables $Z_1, \dots, Z_n$ in a time window of length n and letting $n \rightarrow \infty$, if the threshold increases with n at an appropriate rate. Let γ_n be a sequence with $\gamma_n \rightarrow \infty$ and such that $nP(|Z| > \gamma_n) \rightarrow 0$ as $n \rightarrow \infty$. Then, the probability to see two different Z 's of size of the order γ_n among the variables $Z_1, \dots, Z_n$, is small compared to seeing just one Z of size of the order γ_n . Indeed, for any $\varepsilon > 0$,

$$\begin{aligned} & \frac{P(\text{there exist } 1 \leq i < j \leq n \text{ such that } |Z_i| > \gamma_n \varepsilon \text{ and } |Z_j| > \gamma_n \varepsilon)}{P(|Z_i| > \gamma_n \text{ for some } 1 \leq i \leq n)} \\ & \sim \frac{(n(n-1)/2)P(|Z| > \gamma_n \varepsilon)^2}{nP(|Z| > \gamma_n)} \rightarrow 0. \end{aligned}$$

Here $a_n \sim b_n$ is shorthand for $\lim_{n \rightarrow \infty} a_n/b_n = 1$.

A convenient description of the large values for the sequence $Z_1, Z_2, \dots$ can be obtained by considering the convergence of the point measures

$$N_n = \sum_{k=1}^n \delta_{(k/n, \gamma_n^{-1} Z_k)}, \quad n = 1, 2, \dots,$$

on the state space $[0, 1] \times (\mathbf{R}^d \setminus \{0\})$. The assumption $nP(|Z| > \gamma_n) \rightarrow 0$ as $n \rightarrow \infty$ implies that $\gamma_n \rightarrow \infty$ too fast for a non-trivial weak convergence of N_n (described, for example, by Proposition 3.21 in Resnick (1987)). When γ_n grows so fast, the second coordinates of all points of the point measure N_n will tend to zero with probability 1. Since points with the zero second coordinate are defined to be not in the state space on which the point measures live (see, once again, Resnick (1987)), it turns out that the point measure N_n converges almost surely to the null measure, denoted ξ_0 . Intuitively, this is exactly the situation where large deviations in the space of point measures might help: the hope is to find a sequence $r_n \rightarrow \infty$ such that $r_n P(N_n \in \cdot)$ converges to some limiting measure m on the space of point measures.

The above discussion makes it reasonable to expect that this limiting measure, m , is concentrated on point measures with one point, corresponding, for each $n =$

$1, 2, \dots$, to a single large (at the scale $\gamma_n = n$) value of Z_{k^*} , $k^* = 1, \dots, n$. In fact, the limiting measure is expected to be

$$m(B) = (\text{Leb} \times \mu)\{(t, z) : \delta_{(t, z)} \in B\}, \quad B \text{ a measurable set of measures.}$$

The “uniform” coordinate t is interpreted as the rescaled within the set $\{1, \dots, n\}$ time k^* of the large Z_{k^*} -value. Since all Z_k ’s have equal probability of being large, t is “uniformly distributed” on $[0, 1]$. The corresponding value z is governed by the limiting measure μ which describes the large values of the Z -variables. The suggested convergence can be rigorously established, as is done (in a significantly more general setting) in Theorem 4.1 below.

It is possible to look at this convergence as the partial sum convergence of the underlying sequence $(\delta_{(k/n, \gamma_n^{-1} Z_k)})$ in the space of point measures. This is similar to Sanov’s theorem in the light-tailed case (see e.g. Dembo and Zeitouni (1998), Section 6.2).

3.2. A finite moving average. Suppose that, in (1.1), $p = d = 1$, and $A_{k,j} = A_j$ are deterministic coefficients with $A_j = 0$ if $j < 0$ or $j > q$. Then (X_k) is a sequence with the representation

$$X_k = A_0 Z_k + A_1 Z_{k-1} + \dots + A_q Z_{k-q}.$$

Consider a time-window of length n where, for now, n is fixed. That is, we consider the vector $(X_1, \dots, X_n)$. Then, $(X_1, \dots, X_n)^T = A'(Z_{1-q}, \dots, Z_n)^T$ where A' is the $n \times (n+1+q)$ -matrix

$$A' = \begin{pmatrix} A_q & A_{q-1} & \dots & A_0 & 0 & \dots & \dots & 0 \\ 0 & A_q & A_{q-1} & \dots & A_0 & 0 & \dots & 0 \\ \vdots & \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & \vdots \\ 0 & \dots & 0 & A_q & A_{q-1} & \dots & \dots & A_0 \end{pmatrix}.$$

Since the Z variables are independent the vector $(Z_{1-q}, \dots, Z_n)^T$ is regularly varying with limit measure concentrated on the coordinate axes, just as in the previous example. That is, asymptotically, only one variable among $Z_{1-q}, \dots, Z_n$ will be large on the large deviations scale, and they all have equal probability of being large. Suppose Z_{k^*} is large for some $1-q \leq k^* \leq n$. Then, since all the other Z_k ’s are small in comparison to Z_{k^*} we expect that X_k is small for $k < k^*$ and $k > k^* + q$ whereas for $k^* \leq k \leq k^* + q$ we have

$$X_k \approx A_{k-k^*} Z_{k^*}.$$

If we study the convergence of the sequence of measures $(r_n P(N_n \in \cdot))$, where

$$N_n = \sum_{k=1}^n \delta_{(k/n, \gamma_n^{-1} X_k)}, \quad n = 1, 2, \dots,$$

is defined on the state space $[0, 1] \times (\mathbf{R} \setminus \{0\})$, we would expect that the limiting measure is concentrated on point measures with $q+1$ points of the form (t, x_i) , with the same time coordinate t and space coordinates of the form $x_i = A_i z$ for some z . In other words, we expect the limiting measure to be

$$m(B) = (\text{Leb} \times \mu)\{(t, z) : \sum_{i=0}^q \delta_{(t, A_i z)} \in B\}, \quad B \text{ a measurable set of measures.}$$

The clustering of extreme values is captured in the limiting measure as there are $q + 1$ points corresponding to large values of the X_k 's. However, in the limit all these points have the same time-coordinate t , which means that the limiting measure does not keep track of the order in which the large values arrived. That is, the complete internal structure of the cluster of extreme values is not captured. The order at which the large values arrive is, however, of crucial importance when studying, for instance, the ruin probabilities, or the long strange segments corresponding to the process (X_k) ; see e.g. Asmussen (2000), Dembo and Zeitouni (1998), Mikosch and Samorodnitsky (2000), Hult et al. (2005). Therefore, information is lost in the limit.

Our suggestion for resolving this loss of information is via considering point measures similar to the measures N_n above, but enlarging the dimension of the state space so that each point of the point measure describes more than one value of the process (X_k) . It is intuitive that for a finite moving average of the above example it is enough to keep track of $q + 1$ consecutive observations of the stationary process, and this tells us how large the state space of the point measures should be. Specifically, we will consider the point measures

$$\sum_{k=1}^n \delta_{(k/n, \gamma_n^{-1}(X_k, X_{k-1}, \dots, X_{k-q}))}, \quad n = 1, 2, \dots$$

The above discussion should make it intuitive that, for such point processes, the limiting measure in a large deviations procedure should be concentrated on point measures with $2q + 1$ points of the form

$$(t, (A_0 z, 0, \dots, 0)), (t, (A_1 z, A_0 z, 0, \dots, 0)), \dots, (t, (0, \dots, 0, A_q z)).$$

Notice that the information about the order in which the extreme values arrived can be obtained because the space coordinates are simply shifts of each other.

In general, the complete information on the extreme values of the process will only be completely preserved if one keeps track of infinite (or increasing with n) number of observations of the process (X_k) . This is possible to do, but we have chosen not pursue this last possibility because it complicates significantly the technical details of the construction of the point measures and working with these measures. Instead, we have chosen to construct point measures based on finitely many consecutive observations of the stationary process, as if it were a finite moving average. In applications we are considering, this turns out to be sufficient via an application of a truncation argument.

4. LARGE DEVIATIONS FOR POINT PROCESSES: THE MAIN RESULT

We start with specifying the precise assumptions on the normalizing sequence $(\gamma_n)_{n \geq 1}$ that are needed to obtain a large deviation scaling. We assume that

$$\left. \begin{aligned} (Z_1 + \dots + Z_n)/\gamma_n &\rightarrow 0, & \text{in probability and} \\ \gamma_n/\sqrt{n^{1+\varepsilon}} &\rightarrow \infty, & \text{for some } \varepsilon > 0 \text{ if } \alpha = 2, \\ \gamma_n/\sqrt{n \log n} &\rightarrow \infty, & \text{if } \alpha > 2. \end{aligned} \right\} \quad (4.1)$$

Note that these conditions are exactly the same as those that were used in Theorem 2.1 in (Hult et al., 2005) to obtain a functional level large deviation result for the

partial sums of independent and identically distributed random vectors. If we set

$$r_n = \frac{1}{nP(|Z| > \gamma_n)},$$

then $r_n \rightarrow \infty$ as $n \rightarrow \infty$ and it turns out that normalizing the probability measures of the point processes by (r_n) is the correct normalization to obtain a large deviation result.

For $q \geq 0$ define a point measure N_n^q on the space $\mathbf{E}^q = [0, 1] \times (\mathbf{R}^{d(q+1)} \setminus \{0\})$ by

$$N_n^q = \sum_{k=1}^n \delta_{(k/n, \gamma_n^{-1} X_k, \gamma_n^{-1} X_{k-1}, \dots, \gamma_n^{-1} X_{k-q})}. \quad (4.2)$$

We will show that the sequence of measures on the space of point measures,

$$m_n^q(\cdot) = r_n P(N_n^q \in \cdot), \quad n \geq 1,$$

converges in the appropriate sense and compute the limiting measure, called m^q , for any $q \geq 0$. The limiting measure will give us a partial description of the extremal behavior of the sequence (X_k) . This description will become more and more detailed as the number q is taken larger and larger.

A technical framework suitable for studying this problem is provided in the Appendix, and we are using the notation introduced there. Let $\mathbf{N}_p^q = \mathbf{N}_p(\mathbf{E}^q)$ be the space of point measures on $\mathbf{E}^q$ equipped with the vague topology. The convergence $m_n^q \rightarrow m^q$ takes place in the space $\mathbf{M}_0(\mathbf{N}_p^q)$, the space of Radon measures on $\mathbf{N}_p^q$ that are finite on sets of the form $\{\xi : d(\xi, \xi_0) > r\}$, for each $r > 0$ (see the Appendix). Here ξ_0 denotes the null measure and $d(\cdot, \cdot)$ the metric on $\mathbf{N}_p^q$ given by (A.1). With this metric, $(\mathbf{N}_p^q, d)$ is a complete separable metric space.

For a sequence of $d \times p$ -matrices $\mathbb{A} = (A_{k,j})_{j,k \in \mathbf{Z}}$ and $(t, z) \in [0, 1] \times \mathbf{R}^p \setminus \{0\}$ we write

$$T_{\mathbb{A},q}(t, z) = \sum_{j \in \mathbf{Z}} \delta_{(t, A_{j,j}z, A_{j-1,j-1}z, \dots, A_{j-q,j-q}z)}.$$

Under certain conditions on the matrices in $A_{k,j}$, $T_{\mathbb{A},q}$ will be a map from $[0, 1] \times \mathbf{R}^p \setminus \{0\}$ into the space $\mathbf{N}_p^q$.

We are now ready to state the main result of this paper.

Theorem 4.1. *Suppose that (2.1), (2.2)–(2.4), and (4.1) hold. Then, for any $q \geq 0$, the stationary process $(X_k)_{k \in \mathbf{Z}}$ in (1.1) satisfies*

$$m_n^q(\cdot) = r_n P(N_n^q \in \cdot) \rightarrow E[(\text{Leb} \times \mu) \circ T_{\mathbb{A},q}^{-1}(\cdot)] =: m^q(\cdot) \quad (4.3)$$

in $\mathbf{M}_0(\mathbf{N}_p^q)$. In particular, $T_{\mathbb{A},q}$ is, with probability 1, a map from $[0, 1] \times \mathbf{R}^p \setminus \{0\}$ into the space $\mathbf{N}_p^q$.

Remark 4.1. For any $a > 0$ the measure m^q on $\mathbf{N}_p^q$ defined in (4.3) satisfies

$$\begin{aligned} & m^q \left\{ \xi : \xi([0, 1] \times \{(x_0, \dots, x_q) : |x_i| = a, \text{ some } i \in \{0, \dots, q\}\}) > 0 \right\} \\ &= E \left[\mu \left\{ z : \sum_{j \in \mathbf{Z}} \delta_{(A_{j,j}z, \dots, A_{j-q,j-q}z)}((x_0, \dots, x_q) : |x_i| = a, \text{ some } i \in \{0, \dots, q\}) > 0 \right\} \right] \\ &\leq \sum_{j \in \mathbf{Z}} E \mu \{ z : |A_{j,j}z| = a \} = 0 \end{aligned}$$

by the scaling property of the measure μ . This fact is useful for establishing continuity almost everywhere with respect to the measure m^q of various mappings.

Example 4.1 (Independent and identically distributed random vectors). For a sequence of independent and identically distributed random vectors we have $A_{k,j} = A\{j = 0\}$, where A is a fixed $d \times p$ -matrix, and, hence, for $q = 0$, the limiting measure m^0 is given by $m^0(\cdot) = (\text{Leb} \times \mu) \circ T_{iid}^{-1}(\cdot)$ where T_{iid} is the mapping

$$T_{iid}(t, z) = \delta_{(t, z)}.$$

Example 4.2 (Linear process). For a linear process the matrices $A_{k,j} = A_j$, $j \in \mathbf{Z}$ are deterministic. The limiting measure m^q is given by $m^q(\cdot) = (\text{Leb} \times \mu) \circ T_{A,q}^{-1}(\cdot)$, with the mapping $T_{A,q}$ simplifying to

$$T_{A,q}(t, z) = \sum_{j \in \mathbf{Z}} \delta_{(t, A_j z, A_{j-1} z, \dots, A_{j-q} z)}.$$

Proof of Theorem 4.1. By Theorem A.2 we need to prove that the measure m^q in (4.3) belongs to $\mathbf{M}_0(\mathbf{N}_p^q)$, and that

$$m_n(F_{g_1, g_2, \varepsilon_1, \varepsilon_2}) \rightarrow m^q(F_{g_1, g_2, \varepsilon_1, \varepsilon_2}) \quad (4.4)$$

for all Lipschitz functions $g_1, g_2 \in C_K^+(\mathbf{E}^q)$ and $\varepsilon_1, \varepsilon_2 > 0$, where the functions $F_{g_1, g_2, \varepsilon_1, \varepsilon_2}$ are given in (A.2) in the Appendix. For the first statement, it is enough to prove that for each $\delta > 0$,

$$ES_\delta =: E \left(\sum_{j \in \mathbf{Z}} I\{\|A_j\| > \delta\} \right) < \infty.$$

This is an easy consequence of conditions (2.2)–(2.4). For example, if $0 < \alpha \leq 2$, then for $0 < \varepsilon < \alpha$,

$$ES_\delta \leq \delta^{-(\alpha-\varepsilon)} \sum_{j \in \mathbf{Z}} E\|A_j\|^{\alpha-\varepsilon} < \infty,$$

and the case $\alpha > 2$ is similar.

We now prove (4.4). Note that

$$\begin{aligned} m_n(F_{g_1, g_2, \varepsilon_1, \varepsilon_2}) = & \quad (4.5) \\ r_n E & \left[\left(1 - \exp \left\{ - \left[\sum_{k=1}^n g_1 \left(\frac{k}{n}, \frac{X_k}{\gamma_n}, \dots, \frac{X_{k-q}}{\gamma_n} \right) - \varepsilon_1 \right]_+ \right\} \right) \right. \\ & \times \left. \left(1 - \exp \left\{ - \left[\sum_{k=1}^n g_2 \left(\frac{k}{n}, \frac{X_k}{\gamma_n}, \dots, \frac{X_{k-q}}{\gamma_n} \right) - \varepsilon_2 \right]_+ \right\} \right) \right]. \end{aligned}$$

The first step is to truncate the infinite sum in the definition of X_k , replacing X_k by $\sum_{|j| \leq J_n} A_{k,j} Z_{k-j}$, as follows. Let (J_n) be a sequence of positive numbers such that $J_n \rightarrow \infty$ and

$$\left. \begin{aligned} J_n &= o(n) && \text{if } 0 < \alpha < 1, \\ J_n &= o(\min(n, \gamma_n/l(\gamma_n))) && \text{if } \alpha = 1, \\ J_n &= o(\min(n, \gamma_n)) && \text{if } \alpha > 1, \end{aligned} \right\} \quad (4.6)$$

where for $x > 0$, $l(x) = E(|Z|I\{|Z| \leq x\})$. The conditions on the asymptotic growth of J_n will be used below.

By Lemma 4.1 there is a sequence $\beta_n \downarrow 0$ such that

$$r_n P\left(\max_{1 \leq k \leq n} \frac{1}{\gamma_n} \left| \sum_{|j| > J_n} A_{k,j} Z_{k-j} \right| > \beta_n\right) \rightarrow 0$$

as $n \rightarrow \infty$. Therefore, the expression in the right hand side of (4.5) is within $o(1)$ of

$$\begin{aligned} & r_n E \left[\left(1 - \exp \left\{ - \left[\sum_{k=1}^n g_1 \left(\frac{k}{n}, R_{k,n} + \frac{1}{\gamma_n} \sum_{|j| \leq J_n} A_{k,j} Z_{k-j}, \dots, \right. \right. \right. \right. \\ & \quad \left. \left. \left. R_{k-q,n} + \frac{1}{\gamma_n} \sum_{|j| \leq J_n} A_{k-q,j} Z_{k-q-j} \right) - \varepsilon_1 \right]_+ \right\} \right) \right. \\ & \quad \times \left(1 - \exp \left\{ - \left[\sum_{k=1}^n g_2 \left(\frac{k}{n}, R_{k,n} + \frac{1}{\gamma_n} \sum_{|j| \leq J_n} A_{k,j} Z_{k-j}, \dots, \right. \right. \right. \right. \\ & \quad \left. \left. \left. R_{k-q,n} + \frac{1}{\gamma_n} \sum_{|j| \leq J_n} A_{k-q,j} Z_{k-q-j} \right) - \varepsilon_2 \right]_+ \right\} \right) \Big] \\ & := r_n E(\Theta_n), \end{aligned}$$

where $(R_{k,n})$ are random variables satisfying $|R_{k,n}| \leq \beta_n$ for all k, n .

To proceed we use the intuitive idea that only one of the Z 's is likely to be large. Take $\tau > 0$. The above expression can be decomposed as

$$\begin{aligned} & r_n E(\Theta_n I\{\text{all } |Z_{-J_n-q+1}|, \dots, |Z_{n+J_n}| \text{ are less than } \tau\gamma_n\}) \\ & + r_n E(\Theta_n I\{\text{exactly one of } |Z_{-J_n-q+1}|, \dots, |Z_{n+J_n}| \text{ exceeds } \tau\gamma_n\}) \\ & + r_n E(\Theta_n I\{\text{at least two of } |Z_{-J_n-q+1}|, \dots, |Z_{n+J_n}| \text{ exceed } \tau\gamma_n\}) \\ & = r_n E\left(\Theta_n I\left\{\bigcap_{t=-J_n-q+1}^{n+J_n} |Z_t| \leq \tau\gamma_n\right\}\right) \end{aligned} \quad (4.7)$$

$$+ r_n E\left(\Theta_n I\left\{\bigcup_{t=-J_n-q+1}^{n+J_n} \bigcap_{\substack{s=-J_n-q+1, \dots, n+J_n \\ s \neq t}} \{|Z_t| > \tau\gamma_n, |Z_s| \leq \tau\gamma_n\}\right\}\right) \quad (4.8)$$

$$+ r_n E\left(\Theta_n I\left\{\bigcup_{t=-J_n-q+1}^{n+J_n} \bigcup_{\substack{s=-J_n-q+1, \dots, n+J_n \\ s \neq t}} \{|Z_t| > \tau\gamma_n, |Z_s| > \tau\gamma_n\}\right\}\right). \quad (4.9)$$

We claim that the main contribution comes from (4.8) and that the contributions from the other terms vanish as $n \rightarrow \infty$ and then $\tau \rightarrow 0$. Let us start with (4.7). Recall that g_1 and g_2 have compact supports in $\mathbf{E}^q = [0, 1] \times (\mathbf{R}^{d(q+1)} \setminus \{0\})$. Hence, there is a $\delta > 0$ such that $([0, 1] \times \{(x_0, \dots, x_q) : \max\{|x_0|, \dots, |x_q|\} < \delta\}) \cap \{\text{support}(g_1) \cup \text{support}(g_2)\} = \emptyset$. On the set $\cap_{t=-J_n-q+1}^{n+J_n} \{|Z_t| \leq \tau\gamma_n\}$ we have, for large n ,

$$\begin{aligned} & r_n E\left(\Theta_n I\left\{\bigcap_{t=-J_n-q+1}^{n+J_n} |Z_t| \leq \tau\gamma_n\right\}\right) \\ & \leq r_n E\left(\Theta_n I\left\{\bigcup_{k=1-q}^n \left\{|R_{k,n} + \frac{1}{\gamma_n} \sum_{|j| \leq J_n} A_{k,j} Z_{k-j} I\{|Z_{k-j}| \leq \tau\gamma_n\}\right| > \delta\right\}\right)\right) \end{aligned}$$

$$\begin{aligned}
&\leq r_n P\left(\bigcup_{k=1-q}^n \left\{ \left| R_{k,n} + \frac{1}{\gamma_n} \sum_{|j| \leq J_n} A_{k,j} Z_{k-j} I\{|Z_{k-j}| \leq \tau \gamma_n\} \right| > \delta \right\}\right) \\
&\leq r_n(n+q) P\left(\left| \sum_{|j| \leq J_n} A_{0,j} Z_j I\{|Z_j| \leq \tau \gamma_n\} \right| > \gamma_n \delta/2\right) \rightarrow 0,
\end{aligned}$$

as $n \rightarrow \infty$ and then $\tau \rightarrow 0$, by appealing to (2.8) (the last inequality used the fact that $\beta_n \downarrow 0$). For (4.9) we observe that for any $\tau > 0$

$$\begin{aligned}
&r_n E\left(\Theta_n I\left\{\bigcup_{t=-J_n-q+1}^{n+J_n} \bigcup_{\substack{s=-J_n-q+1, \dots, n+J_n \\ s \neq t}} \{|Z_t| > \tau \gamma_n, |Z_s| > \tau \gamma_n\}\right\}\right) \\
&\leq r_n P\left(\bigcup_{t=-J_n-q+1}^{n+J_n} \bigcup_{\substack{s=-J_n-q+1, \dots, n+J_n \\ s \neq t}} \{|Z_t| > \tau \gamma_n, |Z_s| > \tau \gamma_n\}\right) \\
&\leq r_n(n+q+2J_n)^2 P(|Z| > \tau \gamma_n)^2 \rightarrow 0
\end{aligned}$$

as $n \rightarrow \infty$ by the definition of r_n and the fact that J_n/n is bounded. Hence, as claimed, the main contribution comes from (4.8). Since the union is disjoint we may rewrite (4.8) as

$$\begin{aligned}
&\sum_{t=-J_n-q+1}^{n+J_n} r_n E\left[\left(1 - \exp\left\{-\left[\sum_{k=1}^n g_1\left(\frac{k}{n}, R_{k,n} + \frac{1}{\gamma_n} \sum_{|j| \leq J_n} A_{k,j} Z_{k-j}, \dots, \right. \right. \right. \right. \\
&\quad \left. \left. \left. R_{k-q,n} + \frac{1}{\gamma_n} \sum_{|j| \leq J_n} A_{k-q,j} Z_{k-q-j}\right) - \varepsilon_1\right]_+\right\}\right) \\
&\quad \times \left(1 - \exp\left\{-\left[\sum_{k=1}^n g_2\left(\frac{k}{n}, R_{k,n} + \frac{1}{\gamma_n} \sum_{|j| \leq J_n} A_{k,j} Z_{k-j}, \dots, \right. \right. \right. \right. \\
&\quad \left. \left. \left. R_{k-q,n} + \frac{1}{\gamma_n} \sum_{|j| \leq J_n} A_{k-q,j} Z_{k-q-j}\right) - \varepsilon_2\right]_+\right\}\right) \\
&\quad \times I\{|Z_t| > \tau \gamma_n, |Z_s| \leq \tau \gamma_n, \text{ all } s = -J_n - q + 1, \dots, n + J_n, s \neq t\} \Big]. \quad (4.10)
\end{aligned}$$

As $|Z_t|$ is large and $|Z_s|$ is small, $s \neq t$, we can practically ignore the contribution from the $|Z_s|$ -terms. To be precise we claim that the above expression is asymptotically equal (written $a_n \sim b_n$) to

$$\begin{aligned}
&\sum_{t=-J_n-q+1}^{n+J_n} r_n E\left[\left(1 - \exp\left\{-\left[\sum_{k=1}^n g_1\left(\frac{k}{n}, R_{k,n} + \frac{1}{\gamma_n} \sum_{|j| \leq J_n} A_{k,j} Z_{k-j} I\{t=k-j\}, \dots, \right. \right. \right. \right. \right. \\
&\quad \left. \left. \left. R_{k-q,n} + \frac{1}{\gamma_n} \sum_{|j| \leq J_n} A_{k-q,j} Z_{k-q-j} I\{t=k-q-j\}\right) - \varepsilon_1\right]_+\right\}\right) \\
&\quad \times \left(1 - \exp\left\{-\left[\sum_{k=1}^n g_2\left(\frac{k}{n}, R_{k,n} + \frac{1}{\gamma_n} \sum_{|j| \leq J_n} A_{k,j} Z_{k-j} I\{t=k-j\}, \dots, \right. \right. \right. \right. \\
&\quad \left. \left. \left. R_{k-q,n} + \frac{1}{\gamma_n} \sum_{|j| \leq J_n} A_{k-q,j} Z_{k-q-j} I\{t=k-q-j\}\right) - \varepsilon_1\right]_+\right\}\right)
\end{aligned}$$

$$\begin{aligned}
& \times I\{|Z_t| > \tau\gamma_n\} \Big] \\
& =: \sum_{t=-J_n-q+1}^{n+J_n} r_n E[\Theta'_n I\{|Z_t| > \tau\gamma_n\}]. \tag{4.11}
\end{aligned}$$

For now we postpone the proof that (4.10) $\sim$ (4.11) and proceed, instead, with analyzing (4.11). We can rewrite (4.11) as

$$\begin{aligned}
& \sum_{t=-J_n-q+1}^{n+J_n} r_n E \Big[\left(1 - \exp \left\{ - \left[\sum_{k=1}^n g_1 \left(\frac{k}{n}, R_{k,n} + \frac{1}{\gamma_n} A_{k,k-t} Z_t I\{|k-t| \leq J_n\}, \dots, \right. \right. \right. \\
& \quad \left. \left. \left. R_{k-q,n} + \frac{1}{\gamma_n} A_{k-q,k-q-t} Z_t I\{|k-q-t| \leq J_n\} \right) - \varepsilon_1 \right]_+ \right\} \right) \\
& \times \left(1 - \exp \left\{ - \left[\sum_{k=1}^n g_2 \left(\frac{k}{n}, R_{k,n} + \frac{1}{\gamma_n} A_{k,k-t} Z_t I\{|k-t| \leq J_n\}, \dots, \right. \right. \right. \\
& \quad \left. \left. \left. R_{k-q,n} + \frac{1}{\gamma_n} A_{k-q,k-q-t} Z_t I\{|k-q-t| \leq J_n\} \right) - \varepsilon_2 \right]_+ \right\} \right) \\
& \times I\{|Z_t| > \tau\gamma_n\} \Big]
\end{aligned}$$

In the sequel, as the subscripts change, we will write R_n instead of the proper $R_{k,n}$ corresponding to the appropriate subscripts. We will not impose any assumptions on these random variables apart from the fact that $|R_n| \leq \beta_n$ for all n . With $l = k - t$ we can rewrite the above expression as

$$\begin{aligned}
& \sum_{t=-J_n-q+1}^{n+J_n} r_n E \Big[\left(1 - \exp \left\{ - \left[\sum_{l=1-t}^{n-t} g_1 \left(\frac{t+l}{n}, R_n + \frac{1}{\gamma_n} A_{t+l,l} Z_t I\{|l| \leq J_n\}, \dots, \right. \right. \right. \\
& \quad \left. \left. \left. R_n + \frac{1}{\gamma_n} A_{t+l-q,l-q} Z_t I\{|l-q| \leq J_n\} \right) - \varepsilon_1 \right]_+ \right\} \right) \\
& \times \left(1 - \exp \left\{ - \left[\sum_{l=1-t}^{n-t} g_2 \left(\frac{t+l}{n}, R_n + \frac{1}{\gamma_n} A_{t+l,l} Z_t I\{|l| \leq J_n\}, \dots, \right. \right. \right. \\
& \quad \left. \left. \left. R_n + \frac{1}{\gamma_n} A_{t+l-q,l-q} Z_t I\{|l-q| \leq J_n\} \right) - \varepsilon_2 \right]_+ \right\} \right) \\
& \times I\{|Z_t| > \tau\gamma_n\} \Big].
\end{aligned}$$

By stationarity we may replace $A_{t+l-i,l}$ by $A_{l-i,l}$, $i = 0, \dots, q$, and conditioning on Z_t the above equals

$$\begin{aligned}
& \int_{|z| > \tau} \sum_{t=-J_n-q+1}^{n+J_n} r_n E \Big[\left(1 - \exp \left\{ - \left[\sum_{l=1-t}^{n-t} g_1 \left(\frac{t+l}{n}, R_n + A_{l,l} z I\{|l| \leq J_n\}, \dots, \right. \right. \right. \\
& \quad \left. \left. \left. R_n + A_{l-q,l-q} z I\{|l-q| \leq J_n\} \right) - \varepsilon_1 \right]_+ \right\} \right) \\
& \times \left(1 - \exp \left\{ - \left[\sum_{l=1-t}^{n-t} g_2 \left(\frac{t+l}{n}, R_n + A_{l,l} z I\{|l| \leq J_n\}, \dots, \right. \right. \right. \\
& \quad \left. \left. \left. R_n + A_{l-q,l-q} z I\{|l-q| \leq J_n\} \right) - \varepsilon_2 \right]_+ \right\} \right) \Big]
\end{aligned}$$

$$\begin{aligned}
& \times P(\gamma_n^{-1} Z_t \in dz) \\
& =: \int_{|z| > \tau} \kappa_n(z) r_n n P(\gamma_n^{-1} Z \in dz) \\
& =: \int_{|z| > \tau} \kappa_n(z) \mu_n(dz) \sim \int_{|z| > \tau} \tilde{\kappa}_n(z) \mu_n(dz),
\end{aligned}$$

where

$$\begin{aligned}
\tilde{\kappa}_n(z) = & \sum_{t=-J_n+1}^{n+J_n} E \left[\left(1 - \exp \left\{ - \left[\sum_{l=1-t}^{n-t} g_1 \left(\frac{t+l}{n}, A_{l,l} z I\{|l| \leq J_n\}, \dots, \right. \right. \right. \right. \\
& \left. \left. \left. A_{l-q, l-q} z I\{|l-q| \leq J_n\} \right\} - \varepsilon_1 \right]_+ \right) \right\} \\
& \times \left(1 - \exp \left\{ - \left[\sum_{l=1-t}^{n-t} g_2 \left(\frac{t+l}{n}, A_{l,l} z 1\{|l| \leq J_n\}, \dots, \right. \right. \right. \right. \\
& \left. \left. \left. A_{l-q, l-q} z I\{|l-q| \leq J_n\} \right\} - \varepsilon_2 \right]_+ \right) \right\} \right] \frac{1}{n},
\end{aligned}$$

and we have used the uniform continuity of the functions g_1 and g_2 and the fact that $|R_n| \leq \beta_n \downarrow 0$. We claim that, as $n \rightarrow \infty$,

$$\int_{|z| > \tau} \tilde{\kappa}_n(z) \mu_n(dz) \rightarrow \int_{|z| > \tau} \kappa(z) \mu(dz), \quad (4.12)$$

where

$$\begin{aligned}
\kappa(z) = & \int_0^1 E \left[\left(1 - \exp \left\{ - \left[\sum_{l \in \mathbf{Z}} g_1 \left(t, A_{l,l} z, \dots, A_{l-q, l-q} z \right) - \varepsilon_1 \right]_+ \right\} \right) \right. \\
& \left. \times \left(1 - \exp \left\{ - \left[\sum_{l \in \mathbf{Z}} g_2 \left(t, A_{l,l} z, \dots, A_{l-q, l-q} z \right) - \varepsilon_2 \right]_+ \right\} \right) \right] dt.
\end{aligned}$$

Note, first of all, that $\mu_n \rightarrow \mu$ in $\mathbf{M}_0(\mathbf{R}^d)$. Since the functions $(\tilde{\kappa}_n)$ and κ are uniformly bounded, it is enough to prove the convergence in (4.12) when integrating over the set $\{\tau < |z| < M\}$ for any finite $M > \tau$. Using the fact $J_n/n \rightarrow 0$ one needs to check that for any K

$$\int_{\tau < |z| < M} \kappa_n^{(K)}(z) \mu_n(dz) \rightarrow \int_{\tau < |z| < M} \kappa(z) \mu(dz), \quad (4.13)$$

with

$$\begin{aligned}
\kappa_n^{(K)}(z) = & \sum_{t=-K+1}^{n+K} E \left[\left(1 - \exp \left\{ - \left[\sum_{l=1-t}^{n-t} g_1 \left(\frac{t+l}{n}, A_{l,l} z I\{|l| \leq J_n\}, \dots, \right. \right. \right. \right. \right. \\
& \left. \left. \left. A_{l-q, l-q} z I\{|l-q| \leq J_n\} - \varepsilon_1 \right]_+ \right\} \right) \right\} \\
& \times \left(1 - \exp \left\{ - \left[\sum_{l=1-t}^{n-t} g_2 \left(\frac{t+l}{n}, A_{l,l} z I\{|l| \leq J_n\}, \dots, \right. \right. \right. \right. \\
& \left. \left. \left. A_{l-q, l-q} z I\{|l-q| \leq J_n\} - \varepsilon_2 \right]_+ \right\} \right) \right\} \right] \frac{1}{n}.
\end{aligned}$$

Recall that the supports of g_1 and g_2 does not intersect the set $[0, 1] \times \{(x_0, \dots, x_q) : \max\{|x_0|, \dots, |x_q|\} < \delta\}$, some $\delta > 0$. The assumptions (2.2)- (2.4) imply that

$$P(\|A_{l,l}\| \geq \delta/M \text{ for some } |l| \geq K) \rightarrow 0 \text{ as } K \rightarrow \infty. \quad (4.14)$$

Since the limit in (4.13) does not depend on K , one may replace $\kappa_n^{(K)}$ in it (but still using the same notation) with

$$\begin{aligned} \kappa_n^{(K)}(z) &= \sum_{t=-K+1}^{n+K} E \left[\left(1 - \exp \left\{ - \left[\sum_{l \in \mathbf{Z}} g_1 \left(\frac{t+l}{n}, A_{l,l}z, \dots, A_{l-q,l-q}z \right) - \varepsilon_1 \right]_+ \right\} \right) \right. \\ &\quad \left. \times \left(1 - \exp \left\{ - \left[\sum_{l \in \mathbf{Z}} g_2 \left(\frac{t+l}{n}, A_{l,l}z, \dots, A_{l-q,l-q}z \right) - \varepsilon_2 \right]_+ \right\} \right) \right] \frac{1}{n}. \end{aligned}$$

However, $\kappa_n^{(K)} \rightarrow \kappa$ uniformly (in z). Therefore, (4.13) follows, e.g. by Billingsley (1968, Theorem 5.5). Having now established (4.12), we let $\tau \rightarrow 0$ to obtain

$$\int_{|z| > \tau} \kappa(z) \mu(dz) \rightarrow E[(\text{Leb} \times \mu) \circ T_{\mathbb{A}}^{-1}(F_{g_1, g_2, \varepsilon_1, \varepsilon_2})],$$

as required.

It remains only to prove the asymptotic equivalence (4.10) $\sim$ (4.11). Denote $C_n = \{-J_n - q + 1, \dots, n + J_n\}$. Subtracting (4.11) from (4.10) yields

$$\begin{aligned} &\sum_{t=-J_n-q+1}^{n+J_n} r_n \left(E[\Theta_n I\{|Z_t| > \tau\gamma_n, |Z_s| \leq \tau\gamma_n, \text{ all } s \in C_n, s \neq t\}] \right. \\ &\quad \left. - E[\Theta'_n I\{|Z_t| > \tau\gamma_n\}] \right) \\ &= \sum_{t=-J_n-q+1}^{n+J_n} r_n E[(\Theta_n - \Theta'_n) I\{|Z_t| > \tau\gamma_n, |Z_s| \leq \tau\gamma_n \text{ all } s \in C_n, s \neq t\}] \quad (4.15) \\ &+ \sum_{t=-J_n-q+1}^{n+J_n} r_n E[\Theta'_n I\{|Z_t| > \tau\gamma_n\} (1 - I\{|Z_s| \leq \tau\gamma_n, \text{ all } s \in C_n, s \neq t\})]. \end{aligned} \quad (4.16)$$

Since $\Theta'_n \leq 1$, we can bound (4.16) by

$$\sum_{t=-J_n-q+1}^{n+J_n} r_n P(|Z| > \tau\gamma_n) \left(1 - \left(1 - P(|Z| > \tau\gamma_n) \right)^{n+q+2J_n} \right) \rightarrow 0,$$

as $n \rightarrow \infty$ by the choice of r_n and the fact that $J_n/n \rightarrow 0$. To handle (4.15) we use Lemma 4.2. This completes the proof. $\square$

Lemma 4.1. *For the stationary process $(X_k)_{k \in \mathbf{Z}}$ in (1.1) we have, under the assumptions (2.2) - (2.4) and (4.6),*

$$\lim_{n \rightarrow \infty} r_n P \left(\max_{1 \leq k \leq n} \left| \sum_{|j| > J_n} A_{k,j} Z_{k-j} \right| > \gamma_n \varepsilon \right) = 0$$

for any $\varepsilon > 0$.

Proof. By stationarity we have

$$r_n P\left(\max_{1 \leq k \leq n} \left| \sum_{|j| > J_n} A_{k,j} Z_{k-j} \right| > \gamma_n \varepsilon\right) \leq r_n n P\left(\left| \sum_{|j| > J_n} A_{k,j} Z_{k-j} \right| > \gamma_n \varepsilon\right).$$

Using Remark 2.1 and the definition of r_n , we see that the above expression is bounded from above by

$$o(1) n r_n P(|Z| > \gamma_n \varepsilon) \rightarrow 0$$

as $n \rightarrow \infty$. $\square$

Lemma 4.2. *Let $\tilde{\Delta}_n$ be the sum in (4.15). Then $\lim_{\tau \rightarrow 0} \limsup_{n \rightarrow \infty} \tilde{\Delta}_n = 0$.*

Proof. Note that by taking norms it is enough to consider the one dimensional case $d = p = 1$. Furthermore, it is clearly enough to consider a single function g and $\varepsilon > 0$ and prove that

$$\lim_{\tau \rightarrow 0} \limsup_{n \rightarrow \infty} r_n \Delta_n = 0, \quad (4.17)$$

where

$$\begin{aligned} \Delta_n = \sum_{t \in C_n} E \left[\exp \left\{ - \left[\sum_{k=1}^n g\left(\frac{k}{n}, R_{k,n} + \frac{1}{\gamma_n} \sum_{|j| \leq J_n} A_{k,j} Z_{k-j}, \dots, \right. \right. \right. \\ \left. \left. \left. R_{k-q,n} + \frac{1}{\gamma_n} \sum_{|j| \leq J_n} A_{k-q,j} Z_{k-q-j} \right) - \varepsilon \right]_+ \right\} \\ - \exp \left\{ - \left[\sum_{k=1}^n g\left(\frac{k}{n}, R_{k,n} + \frac{1}{\gamma_n} \sum_{|j| \leq J_n} A_{k,j} Z_{k-j} I\{t = k-j\}, \dots, \right. \right. \right. \\ \left. \left. \left. R_{k-q,n} + \frac{1}{\gamma_n} \sum_{|j| \leq J_n} A_{k-q,j} Z_{k-q-j} I\{t = k-q-j\} \right) - \varepsilon \right]_+ \right\} \right] \\ \times I\{|Z_t| > \tau \gamma_n, |Z_s| \leq \tau \gamma_n \text{ all } s \in C_n, s \neq t\} \Big], \end{aligned}$$

where, as above, $C_n = \{-J_n - q + 1, \dots, n + J_n\}$. Let L be the Lipschitz constant of g with respect to the metric on $\mathbf{E}^q$ given by

$$d((s, x_0, \dots, x_q), (t, y_0, \dots, y_q)) = |s - t| + \min\{1, |x_0 - y_0| + \dots + |x_q - y_q|\}.$$

Notice that, in the obvious notation,

$$\begin{aligned} |\Delta_n| &\leq L E \sum_{k=1}^n \min \left\{ 1, \sum_{i=0}^q \frac{1}{\gamma_n} \left| \sum_{|j| \leq J_n} A_{k-i,j} Z_{k-i-j} I\{|Z_{k-i-j}| \leq \tau \gamma_n\} \right| \right\} \\ &\leq L n(q+1) E \min \left[1, \frac{1}{\gamma_n} \left| \sum_{|j| \leq J_n} A_{0,j} Z_{-j} I\{|Z_{-j}| \leq \tau \gamma_n\} \right| \right] \\ &= L n(q+1) \int_0^1 P\left(\left| \sum_{|j| \leq J_n} A_{0,j} Z_{-j} I\{|Z_{-j}| \leq \tau \gamma_n\} \right| > x \gamma_n\right) dx. \end{aligned} \quad (4.18)$$

Suppose first that $0 < \alpha < 1$. We have by (2.8), as $\tau \downarrow 0$,

$$r_n \Delta_n \leq o(1) \frac{n r_n}{\gamma_n} \int_0^{\gamma_n} P(|Z| > x) dx = o(1) n r_n P(|Z| > \gamma_n) \rightarrow 0$$

by Karamata's theorem, and (4.17) follows.

Consider now the case $\alpha \geq 1$. We abbreviate

$$\Delta_n := E(D_n) = \sum_{t=-J_n-q+1}^{n+J_n} E(D_n I(B_t)),$$

where

$$B_t = \left\{ |Z_t| > \tau\gamma_n, |Z_s| \leq \tau\gamma_n \text{ all } s \in C_n, s \neq t \right\}.$$

Since g has a compact support, there is $\delta > 0$ such that $g(s, x_0, \dots, x_q) = 0$ for all $s \in [0, 1]$ and $\{(x_0, \dots, x_q) : |x_0| + \dots + |x_q| < \delta\}$. Let $t \in \{-J_n - q + 1, \dots, n + J_n\}$. We have on the event B_t ,

$$\begin{aligned} |D_n| I\{B_t\} &\leq \left| \sum_{k=1}^n g\left(\frac{k}{n}, R_{k,n} + \frac{1}{\gamma_n} \sum_{|j| \leq J_n} A_{k,j} Z_{k-j}, \dots, \right. \right. \\ &\quad \left. \left. R_{k-q,n} + \frac{1}{\gamma_n} \sum_{|j| \leq J_n} A_{k-q,j} Z_{k-q-j} \right) \right. \\ &\quad \left. - \sum_{k=1}^n g\left(\frac{k}{n}, R_{k,n} + \frac{1}{\gamma_n} \sum_{|j| \leq J_n} A_{k,j} Z_{k-j} I\{t = k-j\}, \dots, \right. \right. \\ &\quad \left. \left. R_{k-q,n} + \frac{1}{\gamma_n} \sum_{|j| \leq J_n} A_{k-q,j} Z_{k-q-j} I\{t = k-q-j\} \right) \right| I\{B_t\}. \end{aligned}$$

Let $K_t = \{k : t - J_n \leq k \leq t + q + J_n\}$ and decompose the last expression into the sum over K_t and $\{1, \dots, n\} \setminus K_t$. Then, on the event B_t , $|\Delta_n|$ is bounded above by

$$\begin{aligned} &L \sum_{k \in K_t} \min \left\{ 1, \sum_{i=0}^q \frac{1}{\gamma_n} \left| \sum_{|j| \leq J_n} A_{k-i,j} Z_{k-i-j} I\{|Z_{k-i-j}| \leq \tau\gamma_n\} I\{j \neq k-i-t\} \right| \right\} \\ &+ \|g\|_\infty \sum_{k \notin K_t} I \left\{ \sum_{i=0}^q \left(|R_{k-i,n}| + \frac{1}{\gamma_n} \left| \sum_{|j| \leq J_n} A_{k-i,j} Z_{k-i-j} I\{|Z_{k-i-j}| \leq \tau\gamma_n\} \right| \right) > \delta \right\} \\ &:= D_{n,1} + D_{n,2}. \end{aligned} \tag{4.19}$$

We start with $D_{n,2}$. Recall that for all i , $|R_{k-i,n}|$ is bounded by $\beta_n \downarrow 0$. Using in the sequel the letter C for a finite positive constant that may change from time to time, we see that for large n ,

$$\begin{aligned} r_n \sum_{t=-J_n-q+1}^{n+J_n} E(D_{n,2} I(B_t)) &\leq C r_n (n + q + 2J_n) n P(|Z| > \tau\gamma_n) \\ &\quad \times P \left(\sum_{i=0}^q \left| \sum_{|j| \leq J_n} A_{k-i,j} Z_{k-i-j} I\{|Z_{k-i-j}| \leq \tau\gamma_n\} \right| > \delta\gamma_n/2 \right) \\ &\leq C \tau^{-\alpha} n (q+1) P \left(\left| \sum_{|j| \leq J_n} A_{k,j} Z_{k,j} I\{|Z_{k,j}| \leq \tau\gamma_n\} \right| > \frac{\delta\gamma_n}{2(q+1)} \right). \end{aligned}$$

Using (2.8) shows that for small $\tau > 0$ this is further bounded by

$$C n P(|Z| > \gamma_n) \rightarrow 0 \quad \text{as } n \rightarrow \infty$$

by the choice of γ_n .

It remains to consider the $D_{n,1}$ term in (4.19). Note that in $D_{n,1}$, for each t, k is restricted to at most $2J_n + q + 1$ possible values. We have

$$\begin{aligned}
r_n & \sum_{t=-J_n-q+1}^{n+J_n} E(D_{n,1}I(B_t)) \\
& \leq C r_n (n + q + 2J_n) P(|Z| > \tau\gamma_n) \\
& J_n E \min \left[1, \sum_{i=0}^q \frac{1}{\gamma_n} \left| \sum_{|j| \leq J_n} A_{k-i,j} Z_{k-i-j} I(|Z_{k-i-j}| \leq \tau\gamma_n) \right| \right] \\
& \leq C(q+1) \frac{J_n}{\gamma_n} \frac{P(|Z| > \tau\gamma_n)}{P(|Z| > \gamma_n)} E \left| \sum_{|j| \leq J_n} A_{0,j} Z_{-j} I(|Z_{-j}| \leq \tau\gamma_n) \right|. \quad (4.20)
\end{aligned}$$

Suppose first that $\alpha = 1$. For large n the last expression can be bounded by

$$C \tau^{-1} \frac{J_n}{\gamma_n} E(|Z| I\{|Z| \leq \tau\gamma_n\}) E \sum_{|j| \leq J_n} |A_j|.$$

Note that $E \sum_{|j| \leq J_n} |A_j|$ stays bounded by (2.2). Furthermore, the function $l(x) = E(|Z| I\{|Z| \leq x\})$ is slowly varying. Therefore, the above expression vanishes as $n \rightarrow \infty$ by (4.6).

Next consider the case $\alpha > 1$. Let $\mu_n = E(Z I\{|Z| \leq \tau\gamma_n\})$. Note that

$$\begin{aligned}
E \left| \sum_{|j| \leq J_n} A_j Z_j I\{|Z_j| \leq \tau\gamma_n\} \right| & \leq E \left| \sum_{|j| \leq J_n} A_j (Z_j I\{|Z_j| \leq \tau\gamma_n\} - \mu_n) \right| + |\mu_n| E \left| \sum_{|j| \leq J_n} A_j \right| \\
& =: I + II.
\end{aligned}$$

Let us start with II . Since $EZ = 0$, we see that, as $n \rightarrow \infty$,

$$|\mu_n| \leq E(|Z| I\{|Z| > \tau\gamma_n\}) \sim C \tau \gamma_n P(|Z| > \tau\gamma_n).$$

Furthermore, to deal with $\sum_{|j| \leq J_n} A_j$, we use the assumptions (2.2) – (2.4). Suppose, for example, that $1 < \alpha \leq 2$. Choose ε small enough so that $\alpha - \varepsilon > 1$, and notice that

$$E \left| \sum_{|j| \leq J_n} A_j \right| \leq C J_n^{1-(\alpha-\varepsilon)-1} E \left(\sum_{|j| \leq J_n} |A_j|^{\alpha-\varepsilon} \right)^{1/(\alpha-\varepsilon)} \leq C J_n^{1-(\alpha-\varepsilon)-1},$$

and so the corresponding term in (4.20) is bounded, for large n , by

$$C \tau^{1-2\alpha} J_n^{2-(\alpha-\varepsilon)-1} P(|Z| > \gamma_n).$$

Note that for ε small enough, $\theta := 2 - (\alpha - \varepsilon)^{-1} < \alpha$. In that case the above expression is $o(J_n/\gamma_n) \rightarrow 0$ as $n \rightarrow \infty$ by (4.6). Similarly, in the case $\alpha > 2$ this term goes to zero as well.

For I , by the Burkholder-Davis-Gundy inequality,

$$E \left| \sum_{|j| \leq J_n} A_j (Z_j I\{|Z_j| \leq \tau\gamma_n\} - \mu_n) \right| \leq C E_A \left[E_Z \left(\sum_{|j| \leq J_n} A_j^2 (Z_j I\{|Z_j| \leq \tau\gamma_n\} - \mu_n)^2 \right)^{\frac{1}{2}} \right].$$

We use, once again, the assumptions (2.2)–(2.4). Assuming again that $1 < \alpha \leq 2$, and choosing ε as above, we see that the above expression is bounded by

$$\begin{aligned} & C E_A \left[E_Z \left(\sum_{|j| \leq J_n} |A_j|^{\alpha-\varepsilon} |Z_j I\{|Z_j| \leq \tau \gamma_n\} - \mu_n|^{\alpha-\varepsilon} \right)^{1/(\alpha-\varepsilon)} \right] \\ & \leq C \left(E |Z I\{|Z| \leq \tau \gamma_n\} - \mu_n|^{\alpha-\varepsilon} \right)^{1/(\alpha-\varepsilon)} E \left(\sum_{|j| \leq J_n} |A_j|^{\alpha-\varepsilon} \right)^{1/(\alpha-\varepsilon)}, \end{aligned}$$

which is bounded, and so the corresponding term in (4.20) converges to zero because $J_n/\gamma_n \rightarrow 0$ as $n \rightarrow \infty$. The case $\alpha > 2$ is entirely analogous (and simpler). This completes the proof of the lemma in all cases. $\square$

5. FIRST APPLICATIONS

Theorem 4.1 provides a rather complete description of the asymptotics of the probability of rare events for the sequence (X_k) . In this section we provide some immediate applications of this theorem. For the sake of simplicity and to avoid complicated formulas we restrict attention to the case where both $A_{k,j}$ and Z_j are univariate and $A_{k,j} \geq 0$ a.s. Then Z has a univariate regularly varying distribution and its limiting measure can be written as in (2.6).

5.1. Order statistics. The first application is to order statistics. Let $X_{i:n}$ be the i th order statistic of $X_1, \dots, X_n$ in descending order. That is,

$$X_{1:n} \geq X_{2:n} \geq \dots \geq X_{n:n}.$$

Fix an integer $q \geq 1$ and consider the q -dimensional vector $(X_{1:n}, \dots, X_{q:n})$ consisting of the q largest values. We denote by A_i^* the i th order statistic of the sequence $\{A_{j,j}, j \in \mathbf{Z}\}$ in descending order; under the assumptions (2.2) – (2.4) this is a well defined random variable. Note that for $\infty > u_1 > u_2 > \dots > u_q > 0$, we can write

$$P(X_{1:n} > \gamma_n u_1, \dots, X_{q:n} > \gamma_n u_q) = P(N_n^0 \in B(u_1, \dots, u_q))$$

with

$$B = B(u_1, \dots, u_q) = \cap_{i=1}^q \{\xi : \xi([0, 1] \times (u_i, \infty)) \geq i\}.$$

Then we have the following implication of Theorem 4.1.

Corollary 5.1. *Let $d = p = 1$, and assume that $A_{k,j} \geq 0$ for all k, j , and that the hypotheses of Theorem 4.1 hold. Then*

$$\frac{P((X_{1:n} > \gamma_n u_1, \dots, X_{q:n} > \gamma_n u_q))}{nP(|Z| > \gamma_n)} \rightarrow w E \min_{i=1, \dots, q} (A_i^* u_i^{-1})^\alpha.$$

Proof. First note that

$$\begin{aligned} m^0(B(u_1, \dots, u_q)) &= E[(\text{Leb} \times \mu) \circ T_{\mathbb{A}}^{-1}(B(u_1, \dots, u_q))] \\ &= E \left[\mu \left\{ z : \sum \delta_{A_{j,j}z}(u_1, \infty) \geq 1, \dots, \sum \delta_{A_{j,j}z}(u_q, \infty) \geq q \right\} \right] \\ &= E[\mu\{z : A_1^* z \in (u_1, \infty), \dots, A_q^* z \in (u_q, \infty)\}] \\ &= w E \min_{i=1, \dots, q} (A_i^* u_i^{-1})^\alpha. \end{aligned}$$

The claim, therefore, is a direct application of Theorem 4.1 once we show that the set $B(u_1, \dots, u_q)$ is bounded away from the null measure and $m(\partial B(u_1, \dots, u_q)) = 0$.

The set $B(u_1, \dots, u_q)$ is open. To see this, write $B(u_1, \dots, u_q) = \cap_{i=1}^q B_i$ with $B_i = \{\xi : \xi([0, 1] \times (u_i, \infty)) \geq i\}$. Then, $B_i^c = \{\xi : \xi([0, 1] \times (u_i, \infty)) < i\}$ and for a sequence of measures $(\xi_n) \subset B_i^c$ with $\xi_n \xrightarrow{v} \xi$ we have, by the Portmanteau theorem,

$$i > \liminf_{n \rightarrow \infty} \xi_n([0, 1] \times (u_i, \infty)) \geq \xi([0, 1] \times (u_i, \infty)).$$

Hence, $\xi \in B_i^c$ so B_i^c is closed. This shows that B_i is open and, consequently, $B(u_1, \dots, u_q)$ is open. Similarly, the set $C_i = \{\xi : \xi([0, 1] \times [u_i, \infty)) \geq i\}$ is closed. Since $B_i \subset C_i$ and C_i does not contain the null measure, we see that each B_i is bounded away from the null measure and, hence, so is B .

Further, it follows, by the above calculation, that

$$\begin{aligned} m(\partial B(u_1, \dots, u_q)) &= m(\overline{B(u_1, \dots, u_q)}) - m(B(u_1, \dots, u_q)) \\ &\leq m(\cap_{i=1}^q C_i) - m(B(u_1, \dots, u_q)) \\ &= E \left[\int_0^\infty I_{[\frac{u_1}{A_1^*}, \infty)}(z) \cdots I_{[\frac{u_q}{A_q^*}, \infty)}(z) w \alpha z^{-\alpha-1} dz \right] \\ &\quad - E \left[\int_0^\infty I_{(\frac{u_1}{A_1^*}, \infty)}(z) \cdots I_{(\frac{u_q}{A_q^*}, \infty)}(z) w \alpha z^{-\alpha-1} dz \right] = 0. \end{aligned}$$

This proves the claim. $\square$

5.2. Hitting times. Next we consider the large deviations of first hitting times. Take $a > 0$ and consider the first hitting time of $(a\gamma_n, \infty)$;

$$\tau_n = \inf\{k : X_k > a\gamma_n\}.$$

Corollary 5.2. *Let $d = p = 1$, and assume that $A_{k,j} \geq 0$ for all k, j , and that the hypotheses of Theorem 4.1 hold. Then for any $\lambda > 0$*

$$\frac{P(\tau_n \leq \lambda n)}{nP(|Z| > \gamma_n)} \rightarrow \lambda E[(A_1^*)^\alpha] w a^{-\alpha}$$

Proof. It is enough to prove the statement for $\lambda = 1$; the proof for a general $\lambda > 0$ will then follow via denoting $m = \lfloor \lambda n \rfloor$ and redefining appropriately the sequence (γ_n) . We have

$$r_n P(\tau_n \leq n) = r_n P\left(\sup_{0 \leq k \leq n} X_k / \gamma_n > a\right) = r_n P(X_{1:n} > \gamma_n a),$$

and the statement follows from Corollary 5.1. $\square$

6. LARGE DEVIATIONS OF THE PARTIAL SUMS

In this section large deviation results for the partial sums $S_n = X_1 + \dots + X_n$, $n = 1, 2, \dots$ are considered. The main idea is to start from Theorem 4.1 and derive results for the partial sum by summing up the points in the point measure N_n , while applying the continuous mapping argument.

It turns out that for success of this program additional assumptions are needed. The first assumption is designed to control the contribution of “relatively small” values of the X_k ’s. To this end we introduce the following condition: for each $\delta > 0$

$$\lim_{\varepsilon \downarrow 0} \limsup_n r_n P\left(\left|\sum_{k=1}^n X_k I\{|X_k| \leq \gamma_n \varepsilon\}\right| > \gamma_n \delta\right) = 0. \quad (6.1)$$

The second assumption we need is

$$\text{the sum } \sum A_{j,j} \text{ converges a.s. and } E \sup_{J \subset \mathbf{Z}} \left\| \sum_{j \in J} A_{j,j} \right\|^\alpha < \infty. \quad (6.2)$$

Theorem 6.1. *Assume the hypotheses of Theorem 4.1 and, in addition, that (6.1) and (6.2) hold. Then*

$$r_n P(\gamma_n^{-1} S_n \in \cdot) \rightarrow E \left[\mu \left(z : \sum_{j \in \mathbf{Z}} A_{j,j} z \in \cdot \right) \right] \quad (6.3)$$

in $\mathbf{M}_0(\mathbf{R}^d)$.

Remark 6.1. Note that the large deviation result is uniform in the sense that the normalization r_n is the same for all sets. In particular, the univariate result ($p = d = 1$) can be stated as

$$\lim_{n \rightarrow \infty} \frac{P(S_n > \rho \gamma_n)}{nP(|Z| > \rho \gamma_n)} = w E \left(\left[\left(\sum A_{j,j} \right)^+ \right]^\alpha \right) + (1 - w) E \left(\left[\left(\sum A_{j,j} \right)^- \right]^\alpha \right)$$

for every $\rho > 0$, where the limiting measure associated with Z is given by (2.6).

Remark 6.2. In some cases, replacing conditions (6.1) and (6.2) by somewhat stronger conditions, we can modify the proof of Theorem 6.1 to obtain large deviations of the partial sum of the absolute values of the process. It is sufficient to change condition (6.2) to

$$E \left(\sum \|A_{j,j}\| \right)^\alpha < \infty. \quad (6.4)$$

If $0 < \alpha \leq 1$, or $\alpha > 1$ and $n/\gamma_n \rightarrow 0$, then it is sufficient to change condition (6.1) to, for each $\delta > 0$,

$$\lim_{\varepsilon \downarrow 0} \limsup_n r_n P \left(\sum_{k=1}^n |X_k| I\{|X_k| \leq \gamma_n \varepsilon\} > \gamma_n \delta \right) = 0. \quad (6.5)$$

In this case one concludes that $S_n^{\text{abs}} = \sum_{k=1}^n |X_k|$ satisfies

$$r_n P(\gamma_n^{-1} S_n^{\text{abs}} \in \cdot) \rightarrow E \left[\mu \left(z : \sum_{j \in \mathbf{Z}} |A_{j,j} z| \in \cdot \right) \right] \quad (6.6)$$

in $\mathbf{M}_0(\mathbf{R}^d)$.

If, on the other hand, $\alpha > 1$ and $\gamma_n \equiv n$, then it is sufficient to change condition (6.1) to, for each $\delta > 0$,

$$\lim_{\varepsilon \downarrow 0} \limsup_n r_n P \left(\left| \sum_{k=1}^n (|X_k| - E|X_0|) I\{|X_k| \leq n\varepsilon\} \right| > n\delta \right) = 0, \quad (6.7)$$

and then $(S_n^{\text{abs}} - nE|X_0|)$ satisfies

$$r_n P(n^{-1} (S_n^{\text{abs}} - nE|X_0|) \in \cdot) \rightarrow E \left[\mu \left(z : \sum_{j \in \mathbf{Z}} |A_{j,j} z| \in \cdot \right) \right] \quad (6.8)$$

in $\mathbf{M}_0(\mathbf{R}^d)$.

Proof. The idea is to divide S_n into three parts. One term containing the terms where $\varepsilon < |X_k| \leq 1/\varepsilon$ for a small positive ε , and the other two parts containing terms with $|X_k| \leq \varepsilon$ and $|X_k| > 1/\varepsilon$, respectively. The contribution from the latter two parts turns out to be negligible.

For $0 < \varepsilon < 1$ let g_ε be a function $[0, 1] \times \mathbf{R}^d \setminus \{0\} \rightarrow \mathbf{R}^d$ such that $g_\varepsilon(t, x) = g_\varepsilon(x) = x$ on $\varepsilon < |x| \leq 1/\varepsilon$, $g_\varepsilon(x) = 0$ for all other values of x . First we consider the convergence of $r_n P(N_n^0(g_\varepsilon) \in \cdot)$ with N_n^0 as in Theorem 4.1. Let m^0 be the limiting measure in (4.3) with $q = 0$. Note that g_ε is continuous except at the points $|x| = \varepsilon$ and $1/\varepsilon$. By Remark 4.1

$$m^0 \left\{ \xi : \xi([0, 1] \times \{|x| = \varepsilon \text{ or } 1/\varepsilon\}) > 0 \right\} = 0.$$

Hence, the map $\xi \mapsto \xi(g_\varepsilon)$ from $\mathbf{N}_p$ to $\mathbf{R}^d$ satisfies the continuity assumption in the mapping theorem (Lemma A.2). Therefore, Theorem 4.1, with $q = 0$, together with the mapping theorem, imply that

$$r_n P(N_n^0(g_\varepsilon) \in \cdot) \rightarrow E \left[(\text{Leb} \times \mu) \left((t, z) : \sum_{j \in \mathbf{Z}} g_\varepsilon(t, A_{j,j} z) \in \cdot \right) \right] := \tilde{m}_\varepsilon(\cdot) \quad (6.9)$$

in $\mathbf{M}_0(\mathbf{R}^d)$.

Put $\tilde{m}_n(\cdot) = r_n P(\gamma_n^{-1} S_n \in \cdot)$ and $\tilde{m}$ as in the right-hand-side of (6.3). We need to show $\tilde{m}_n(f) \rightarrow \tilde{m}(f)$ for any $f \in C_0(\mathbf{R}^d)$; in fact, it is sufficient to consider uniformly continuous f (see the Appendix). For any such f there is $\eta > 0$ such that $x \in \text{support}(f)$ implies $|x| > \eta$. For any $\delta > 0$

$$\begin{aligned} \tilde{m}_n(f) &= r_n E[f(\gamma_n^{-1} S_n)] \\ &= r_n E[f(\gamma_n^{-1} S_n) I\{|\gamma_n^{-1} S_n - N_n^0(g_\varepsilon)| > \delta\}] \\ &\quad + r_n E[f(\gamma_n^{-1} S_n) I\{|\gamma_n^{-1} S_n - N_n^0(g_\varepsilon)| \leq \delta\}]. \end{aligned}$$

The first term is bounded above by

$$\begin{aligned} |f|_\infty r_n P(|\gamma_n^{-1} S_n - N_n^0(g_\varepsilon)| > \delta) &\leq |f|_\infty r_n P\left(\left|\sum_{k=1}^n X_k I\{|X_k| \leq \gamma_n \varepsilon\}\right| > \frac{\gamma_n \delta}{2}\right) \\ &\quad + |f|_\infty r_n P\left(\left|\sum_{k=1}^n X_k I\{|X_k| > \frac{\gamma_n}{\varepsilon}\}\right| > \frac{\gamma_n \delta}{2}\right). \end{aligned} \quad (6.10)$$

The assumption (6.1) guarantees that the first member in the right hands side of (6.10) is asymptotically negligible. The second member in the right hands side of (6.10) is, up to a constant, bounded above by

$$r_n P\left(\max_{k=1, \dots, n} |X_k| > \gamma_n / \varepsilon\right) \leq r_n n P(|X_0| > \gamma_n / \varepsilon) \rightarrow 0$$

as first $n \rightarrow \infty$ and then $\varepsilon \rightarrow 0$.

Therefore, the statement of the theorem will follow once we show that

$$\lim_{\delta \downarrow 0} \limsup_{\varepsilon \downarrow 0} \limsup_{n \rightarrow \infty} r_n E[f(\gamma_n^{-1} S_n) - f(N_n^0(g_\varepsilon)) I\{|\gamma_n^{-1} S_n - N_n^0(g_\varepsilon)| \leq \delta\}] = 0, \quad (6.11)$$

and

$$\lim_{\varepsilon \downarrow 0} \tilde{m}_\varepsilon(f) = \tilde{m}(f). \quad (6.12)$$

Indeed, in that case we could write for each $\varepsilon > 0$ and $\delta > 0$

$$\begin{aligned} |\tilde{m}_n(f) - \tilde{m}(f)| &\leq r_n E[|f(\gamma_n^{-1} S_n) - f(N_n^0(g_\varepsilon))| I\{|\gamma_n^{-1} S_n - N_n^0(g_\varepsilon)| \leq \delta\}] \\ &\quad + r_n E[f(\gamma_n^{-1} S_n) I\{|\gamma_n^{-1} S_n - N_n^0(g_\varepsilon)| > \delta\}] \\ &\quad + |r_n E[f(N_n^0(g_\varepsilon)) I\{|\gamma_n^{-1} S_n - N_n^0(g_\varepsilon)| \leq \delta\}] - r_n E[f(N_n^0(g_\varepsilon))]| \end{aligned}$$

$$\begin{aligned}
& + |r_n E[f(N_n^0(g_\varepsilon))] - m_\varepsilon(f)| \\
& + |\tilde{m}_\varepsilon(f) - \tilde{m}(f)|.
\end{aligned}$$

By (6.11), the argument in (6.10), (6.9), and (6.12), each term converges to 0 as first $n \rightarrow \infty$, then $\varepsilon \downarrow 0$, and finally $\delta \downarrow 0$.

It remains to prove (6.11) and (6.12). We start with (6.11). Choose δ above to be smaller than $\eta/2$. The reason for this is that if either $f(\gamma_n^{-1}S_n) > 0$ or $f(N_n^0(g_\varepsilon)) > 0$, then on $\{|\gamma_n^{-1}S_n - N_n^0(g_\varepsilon)| \leq \delta\}$ we have $|N_n^0(g_\varepsilon)| > \eta/2$. Since f is uniformly continuous the expression in (6.11) is bounded above by

$$\begin{aligned}
& o_\delta(1) r_n E \left[I\{|N_n^0(g_\varepsilon)| > \eta/2\} I\{|\gamma_n^{-1}S_n - N_n^0(g_\varepsilon)| \leq \delta\} \right] \\
& \leq o_\delta(1) r_n P(|N_n^0(g_\varepsilon)| > \eta/2).
\end{aligned}$$

As $n \rightarrow \infty$ and $\varepsilon \downarrow 0$, (6.9) and (6.12) (still to be proved) show that this remains bounded by $\text{const } o_\delta(1)$. As $\delta \downarrow 0$ this converges to 0.

It remains to show (6.12). We have, as $\varepsilon \downarrow 0$,

$$\begin{aligned}
\tilde{m}_\varepsilon(f) &= \int_{\Omega} \int_{\mathbf{R}^d \setminus \{0\}} f\left(\sum g_\varepsilon(A_{j,j}z)\right) \mu(dz) P(d\omega) \\
&\rightarrow \int_{\Omega} \int_{\mathbf{R}^d \setminus \{0\}} f\left(\sum A_{j,j}z\right) \mu(dz) P(d\omega) \\
&= \tilde{m}(f),
\end{aligned}$$

by dominated convergence. Indeed, $\sum g_\varepsilon(A_{j,j}z) \rightarrow \sum A_{j,j}z$, $\mu \times P$ -a.e. as $\varepsilon \downarrow 0$, f is continuous, and

$$\left| f\left(\sum g_\varepsilon(A_{j,j}z)\right) \right| \leq |f|_\infty I\left\{ \sup_{j \in \mathbf{Z}} \left| \sum_{j \in J} A_{j,j}z \right| > \eta \right\},$$

which is $\mu \times P$ -integrable by the scaling property of the measure μ and the assumption (6.2). $\square$

6.1. Checking the conditions of Theorem 6.1. To apply Theorem 6.1 one needs to verify the extra assumptions imposed there. In this section we provide conditions that are easier to check for some more specific models.

Proposition 6.1. *Let (X_k) be the stationary process in (1.1) satisfying the conditions of Theorem 4.1. If $0 < \alpha < 1$, then (6.5) holds and, hence, (6.1) holds as well. If $0 < \alpha \leq 1$, then (6.4) holds and, hence, (6.2) holds as well.*

Proof. Assume that $0 < \alpha < 1$. By Markov's inequality, Karamata's theorem, and, finally, Theorem 2.1

$$\begin{aligned}
& \lim_{\varepsilon \downarrow 0} \limsup_n r_n P\left(\sum_{k=1}^n |X_k| I\{|X_k| \leq \gamma_n \varepsilon\} > \gamma_n \delta\right) \\
& \leq \lim_{\varepsilon \downarrow 0} \limsup_n r_n (\gamma_n \delta)^{-1} E\left(\sum_{k=1}^n |X_k| I\{|X_k| \leq \gamma_n \varepsilon\}\right) \\
& = \lim_{\varepsilon \downarrow 0} \limsup_n r_n n (\gamma_n \delta)^{-1} E|X_0| I\{|X_0| \leq \gamma_n \varepsilon\} \\
& = \lim_{\varepsilon \downarrow 0} \limsup_n r_n n (\gamma_n \delta)^{-1} C(\gamma_n \varepsilon) P(|X_0| > \gamma_n \varepsilon)
\end{aligned}$$

$$\begin{aligned}
&= \lim_{\varepsilon \downarrow 0} \limsup_n C \frac{\varepsilon P(|X_0| > \gamma_n \varepsilon)}{\delta P(|Z| > \gamma_n)} \\
&= \lim_{\varepsilon \downarrow 0} C \frac{\varepsilon^{1-\alpha}}{\delta} = 0,
\end{aligned}$$

and so (6.1) holds. If $0 < \alpha \leq 1$ then by (2.2) and Cauchy-Schwarz inequality

$$\begin{aligned}
E \left(\sum \|A_j\| \right)^\alpha &\leq \sum E \|A_j\|^\alpha \\
&\leq \sum (E \|A_j\|^{\alpha-\varepsilon})^{1/2} (E \|A_j\|^{\alpha+\varepsilon})^{1/2} \\
&\leq \left(\sum E \|A_j\|^{\alpha-\varepsilon} \right)^{1/2} \left(\sum E \|A_j\|^{\alpha+\varepsilon} \right)^{1/2} < \infty,
\end{aligned}$$

and so (6.4) holds. $\square$

If the sum (1.1) defining the process (X_k) is finite, then modest additional assumptions on the sequence $(\mathbb{A}_k)_{k \in \mathbf{Z}}$ will guarantee applicability of Theorem 6.1. We present one such situation.

Proposition 6.2. *Let (X_k) be the stationary process in (1.1) satisfying the conditions of Theorem 4.1. Suppose, further, that the sequence $(\mathbb{A}_k)_{k \in \mathbf{Z}}$ is i.i.d. such that for some $M = 0, 1, 2, \dots$, $A_{k,j} = 0$ a.s. for $|j| > M$. Then (6.1) holds and, further, (6.5) and (6.7) (as appropriate) hold. Also, both (6.4) and (6.2) hold, and so Theorem 6.1 applies.*

When the i.i.d. assumption of the sequence $(\mathbb{A}_k)_{k \in \mathbf{Z}}$ is dropped one can still obtain sufficient conditions for (6.1). See Lemma 7.3.

Proof. For finite sums the condition (6.4) is a trivial consequence of (2.2) - (2.4). We will show that (6.1) holds; the proof for (6.5) and (6.7) is similar. It is, clearly, enough to consider the case $d = 1$. Notice, further, that

$$\begin{aligned}
&P \left(\left| \sum_{k=1}^n X_k I\{|X_k| \leq \gamma_n \varepsilon\} \right| > \gamma_n \delta \right) \\
&\leq P \left(\text{for some } k = 1, \dots, n, \ |A_{k,j} Z_{k-j}| > \gamma_n \varepsilon \text{ for at least 2 different } j \right) \\
&+ P \left(\left| \sum_{k=1}^n X_k I\{|A_{k,j} Z_{k-j}| \leq \gamma_n M \varepsilon \text{ for all } k = 1, \dots, n \text{ and } |j| \leq M\} \right| > \gamma_n \delta \right).
\end{aligned} \tag{6.13}$$

The first term in the right hand side of (6.13) is bounded by

$$\begin{aligned}
&n \sum_{\substack{i,j=-M,\dots,M \\ i \neq j}} P \left(|A_{0,i} Z_{-i}| > \gamma_n \varepsilon, |A_{0,j} Z_{-j}| > \gamma_n \varepsilon \right) \\
&= o(1) n P(|Z| > \gamma_n) = o(1) (1/r_n),
\end{aligned}$$

as in Lemma 3.4 in Hult and Samorodnitsky (2008). The second term in the right hand side of (6.13) does not exceed

$$\begin{aligned}
&\sum_{j=-M}^M P \left(\left| \sum_{k=1}^n A_{k,j} Z_{k-j} I\{|A_{k,j} Z_{k-j}| \leq \gamma_n M \varepsilon \text{ for all } k = 1, \dots, n \right. \right. \\
&\quad \left. \left. \text{and } |j| \leq M \right\} \right| > \gamma_n \delta / (2M + 1) \right).
\end{aligned}$$

By the assumed independence, for every $|j| \leq M$,

$$\lim_{\varepsilon \downarrow 0} \limsup_n r_n P \left(\left| \sum_{k=1}^n A_{k,j} Z_{k-j} I\{|A_{k,j} Z_{k-j}| \leq \gamma_n M \varepsilon \text{ for all } k = 1, \dots, n \text{ and } |j| \leq M\} \right| > \gamma_n \delta / (2M + 1) \right) = 0,$$

see the argument in Lemma 2.1 in (Hult et al., 2005). Therefore, (6.1) follows. $\square$

Finally, for certain symmetric stochastic recurrence equations as in Examples 1.2 and 2.2 we provide sufficient conditions for the applicability of Theorem 6.1.

Proposition 6.3. *Suppose that the i.i.d. pairs $(Y_k, Z_k)_{k \in \mathbf{Z}}$ are symmetric (i.e. $(-Y_k, -Z_k) \stackrel{d}{=} (Y_k, Z_k)$), $Z \in \text{RV}(\mu, \alpha)$ for some $0 < \alpha < 2$ and $E\|Y\|^{\alpha+\varepsilon} < 1$ for some $\varepsilon > 0$. Then the random recursion (1.3) has a unique stationary solution, and it satisfies Theorem 6.1.*

Proof. Existence and uniqueness of a stationary solution follows from Corollary 2.3 in Hult and Samorodnitsky (2008), which also shows that this solution is of the form (1.1) and satisfies the assumptions of Theorem 4.1. For $0 < \alpha < 1$ the statement follows from Proposition 6.1. For $\alpha \geq 1$ we have by convexity (see Lemma 3.3.1 in Kwapień and Woyczyński (1992))

$$\begin{aligned} E \left(\sum \|A_j\| \right)^\alpha &= E \left(\sum_{j=0}^\infty \left\| \prod_{i=0}^j Y_i \right\| \right)^\alpha \\ &\leq E \left(\sum_{j=0}^\infty \prod_{i=0}^j \|Y_i\| \right)^\alpha \leq \left[\sum_{j=0}^\infty \left(E \prod_{i=0}^j \|Y_i\|^\alpha \right)^{1/\alpha} \right]^\alpha < \infty \end{aligned}$$

since $E\|Y\|^\alpha < 1$. Therefore, (6.4) holds. Further, the symmetry assumption in the proposition guarantees that the stationary process (X_k) is symmetric in the sense that $(X_k) \stackrel{d}{=} (\epsilon_k X_k)$, where (ϵ_k) is a sequence of i.i.d. Rademacher random variables independent of (X_k) . We conclude as in the proof of Proposition 6.1

$$\begin{aligned} &\lim_{\varepsilon \downarrow 0} \limsup_n r_n P \left(\left| \sum_{k=1}^n X_k I\{|X_k| \leq \gamma_n \varepsilon\} \right| > \gamma_n \delta \right) \\ &\leq \lim_{\varepsilon \downarrow 0} \limsup_n r_n (\gamma_n \delta)^{-2} E \left(\left| \sum_{k=1}^n X_k I\{|X_k| \leq \gamma_n \varepsilon\} \right| \right)^2 \\ &= \lim_{\varepsilon \downarrow 0} \limsup_n r_n (\gamma_n \delta)^{-2} E \left(\sum_{k=1}^n X_k^2 I\{|X_k| \leq \gamma_n \varepsilon\} \right) \\ &= \lim_{\varepsilon \downarrow 0} \limsup_n r_n n (\gamma_n \delta)^{-2} E X_k^2 I\{|X_k| \leq \gamma_n \varepsilon\} \\ &= \lim_{\varepsilon \downarrow 0} \limsup_n r_n n (\gamma_n \delta)^{-2} C (\gamma_n \varepsilon)^2 P(|X_k| > \gamma_n \varepsilon) \\ &= \lim_{\varepsilon \downarrow 0} \limsup_n C \frac{\varepsilon^2 P(|X_k| > \gamma_n \varepsilon)}{\delta^2 P(|Z| > \gamma_n)} \\ &= \lim_{\varepsilon \downarrow 0} C \frac{\varepsilon^{2-\alpha}}{\delta^2} = 0, \end{aligned}$$

proving (6.1).

□

7. RUIN PROBABILITIES

In this section we consider the univariate ($d = p = 1$) ruin problem based on the sequence (X_k) in (1.1). Throughout this section we assume that $\alpha > 1$ (which requires, according to our assumptions, that $EZ = 0$), and let $c > 0$ be the “drift”. We are interested in deriving the asymptotic decay of the so-called infinite horizon ruin probability

$$\psi(u) = P\left(\sup_n (S_n - cn) > u\right)$$

as $u \rightarrow \infty$. Here $S_n = X_1 + \dots + X_n$ is the partial sum process.

As in Section 6, we will need to assume extra technical conditions, mostly in order to control the contributions of the small jumps to the ruin probability. We start with some notation. For integer $q \geq -1$ let

$$\hat{X}_k^q = \sum_{|j| > q} A_{k,j} Z_{k-j}, \quad k \in \mathbf{Z}. \quad (7.1)$$

We assume that, for each $q \geq -1$ and each $\delta > 0$,

$$\lim_{\varepsilon \downarrow 0} \limsup_n r_n P\left(\left|\sum_{k=1}^n (|\hat{X}_k^q| - E|\hat{X}_0^q|) I\{|\hat{X}_k^q| \leq n\varepsilon\}\right| > n\delta\right) = 0, \quad (7.2)$$

and that for every $q \geq 0$ and $\gamma > 0$,

$$\lim_{\delta \rightarrow 0} \limsup_{n \rightarrow \infty} \frac{P\left(\sup_{k \leq n} \left|\sum_{i=1}^k X_i^q I\{|X_i^q| \leq n\delta\}\right| > n\gamma\right)}{nP(|Z| > n)} = 0. \quad (7.3)$$

It is easy to check that condition (7.2) holds, for example, under the assumptions of Proposition 6.2. Sufficient conditions for (7.3) are given in Lemma 7.3 below.

Theorem 7.1. *Suppose that the conditions of Theorem 4.1 hold with $\alpha > 1$. Suppose, additionally, that (7.2), (7.3), and (6.4) hold. Then*

$$\lim_{u \rightarrow \infty} \frac{\psi(u)}{uP(|Z| > u)} = E\left[w\left(\sup_{j \in \mathbf{Z}} \sum_{k=-\infty}^j A_{k,k}\right)^\alpha + (1-w)\left(\sup_{j \in \mathbf{Z}} \sum_{k=-\infty}^j -A_{k,k}\right)^\alpha\right] \frac{1}{c(\alpha-1)}. \quad (7.4)$$

Example 7.1 (iid). In the iid case $A_{k,j} = I\{j = 0\}$ and we get the classical result (see e.g. Embrechts et al. (1997))

$$\lim_{u \rightarrow \infty} \frac{\psi(u)}{uP(|Z| > u)} = \frac{w}{c(\alpha-1)}.$$

Example 7.2 (SRE). Consider a univariate SRE of the Examples 1.2 and 2.2. Assume that the i.i.d. pairs $(Y_k, Z_k)_{k \in \mathbf{Z}}$ are symmetric, and that (7.2) holds. Put

$$M_+ = \sup_{j \geq 0} \left(\sum_{k=0}^j Y_1 \cdots Y_k\right)^+,$$

$$M_- = \sup_{j \geq 0} \left(\sum_{k=0}^j Y_1 \cdots Y_k \right)^-.$$

Then

$$\lim_{u \rightarrow \infty} \frac{\psi(u)}{uP(|Z| > u)} = \left(wE[M_+^\alpha] + (1-w)E[M_-^\alpha] \right) \frac{1}{c(\alpha-1)}.$$

This result is believed to be new.

Proof. For $q \geq 0$ we define a counterpart to (7.1) by

$$X_k^q = \sum_{|j| \leq q} A_{k,j} Z_{k-j}, \quad k \in \mathbf{Z},$$

and let

$$S_n^q = X_1^q + \cdots + X_n^q, \quad \hat{S}_n^q = \hat{X}_1^q + \cdots + \hat{X}_n^q, \quad n = 1, 2, \dots$$

Let R denote the right-hand-side of (7.4). The first step is to prove the upper bound

$$\limsup_{u \rightarrow \infty} \frac{\psi(u)}{uP(|Z| > u)} \leq R. \quad (7.5)$$

For (a large) integer $M = 1, 2, \dots$, $\psi(u)$ is bounded above by

$$\begin{aligned} & P\left(\sup_{k \leq [u]M} (S_k - ck) > [u]\right) + P\left(\sup_{k > [u]M} (S_k - ck) > [u]\right) \\ & =: p_M^{(11)}(u) + p_M^{(12)}(u). \end{aligned}$$

By Lemma 7.1

$$\lim_{M \rightarrow \infty} \limsup_{u \rightarrow \infty} \frac{p_M^{(12)}(u)}{uP(|Z| > u)} = 0,$$

so the main contribution comes from $p_M^{(11)}(u)$. For any $\varepsilon > 0$ and any integer $q \geq 0$, we have the upper bound

$$p_M^{(11)}(u) \leq P\left(\sup_{k \leq [u]M} (S_k^q - ck) > [u](1-\varepsilon)\right) + P\left(\sup_{k \leq [u]M} \hat{S}_k^q > [u]\varepsilon\right).$$

It follows from Remark 6.2 and assumptions (7.2) and (6.4) that

$$\lim_{q \rightarrow \infty} \lim_{u \rightarrow 0} \frac{P(\sup_{k \leq [u]M} \hat{S}_k^q > [u]\varepsilon)}{uP(|Z| > u)} = 0.$$

It remains to show

$$\lim_{M \rightarrow \infty} \lim_{\varepsilon \rightarrow 0} \limsup_{q \rightarrow \infty} \limsup_{u \rightarrow \infty} \frac{P\left(\sup_{k \leq [u]M} (S_k^q - ck) > [u](1-\varepsilon)\right)}{uP(|Z| > u)} \leq R. \quad (7.6)$$

Putting $n = [u]M$ and taking $0 < \gamma < 1$, and a small $\delta > 0$, we see that

$$\begin{aligned} & P\left(\sup_{k \leq [u]M} (S_k^q - ck) > [u](1-\varepsilon)\right) \\ & = P\left(\sup_{k \leq n} n^{-1}(S_k^q - ck) > (1-\varepsilon)M^{-1}, \sup_{k \leq n} \left| \sum_{i=1}^k X_i^q I\{|X_i^q| \leq n\delta\} \right| \leq n\gamma\right) \end{aligned} \quad (7.7)$$

$$+ P\left(\sup_{k \leq n} n^{-1}(S_k^q - ck) > (1 - \varepsilon)M^{-1}, \sup_{k \leq n} \left| \sum_{i=1}^k X_i^q I\{|X_i^q| \leq n\delta\} \right| > n\gamma\right).$$

Notice that, by the regular variation and (7.3), for every M (recall $n = [u]M$) and $0 < \gamma < 1$

$$\lim_{\delta \rightarrow 0} \limsup_{u \rightarrow \infty} \frac{P\left(\sup_{k \leq [u]M} \left| \sum_{i=1}^k X_i^q I\{|X_i^q| \leq n\delta\} \right| > n\gamma\right)}{uP(|Z| > u)} = 0. \quad (7.8)$$

Hence, we are left with estimating (7.7).

Since each noise variable Z affects at most $2q + 1$ values of the process (X^q) , it follows from the obvious fact that for every $\delta > 0$,

$$\lim_{n \rightarrow \infty} \frac{P(|Z_j| > n\delta \text{ for at least two different } j = -q, \dots, n+q)}{nP(|Z| > n)} = 0,$$

and Remark 4.1 in Hult and Samorodnitsky (2008), that

$$P(D_n) := P(|X_{j_i}^q| > n\delta \text{ for } j_1, j_2 = 1, \dots, n, |j_1 - j_2| > 2q) = o(nP(|Z| > n)). \quad (7.9)$$

We conclude by (7.9) and (7.8) that for the upper bound we need to prove that

$$\lim_{M \rightarrow \infty} \lim_{\varepsilon \rightarrow 0} \limsup_{q \rightarrow \infty} \lim_{\gamma \rightarrow 0} \limsup_{\delta \rightarrow 0} \limsup_{u \rightarrow \infty} \frac{p_n(\delta)}{uP(|Z| > u)} \leq R. \quad (7.10)$$

Here $p_n(\delta)$ is a modification of the probability in (7.7), defined as follows.

For $n \geq 1$ and $\delta > 0$ we denote

$$K_\delta(n) = \inf\{i = 1, \dots, n : |X_i| > n\delta\},$$

defined to be equal to $n + 1$ if the infimum is taken over the empty set. Then we set

$$p_n(\delta) = P\left(\sup_{0 \leq k \leq 2q} n^{-1} \sum_{i=K_\delta(n)}^{K_\delta(n)+k} X_i - cK_\delta(n) > (1 - \varepsilon)M^{-1} - 2\gamma\right).$$

This puts us in a situation where we can use the large deviations for point processes in Theorem 4.1 and the mapping theorem in Lemma A.2.

Let $q' = 6q + 1$. This will correspond to the dimension of the point processes we will work with. Specifically, q' is the number of values of the process we are keeping track of in (4.2), and we will use the statement of Theorem 4.1 in the space $\mathbf{M}_0(\mathbf{N}_p^{q'})$. We define now a functional $h^* : \mathbf{N}_p^{q'} \rightarrow \mathbb{R}$ as follows. Let

$$\xi = \sum_{k \in \mathbb{Z}} \delta_{(t_k, x_k^{(1)}, \dots, x_k^{(q')})} \in \mathbf{N}_p^{q'}.$$

Consider all points $(t_k, x_k^{(1)}, \dots, x_k^{(q')})$ of ξ satisfying the following two conditions:

- (1) for some $m = 2q + 1, \dots, q' - 2q$, $|x_k^{(m)}| > \delta$;
- (2) $|x_k^{(j)}| \leq \delta$ for all $j = 1, \dots, 2q$ and all $j = q' - 2q + 1, \dots, q'$.

Note that, by the definition of the space $\mathbf{N}_p^{q'}$, the set $H_\delta(\xi)$ of such points is finite. If $H_\delta(\xi) = \emptyset$, we set $h^*(\xi) = 0$.

With the obvious convention for the expression $k \in H_\delta(\xi)$, we set, for each such k ,

$$m_k = \min\{m = 2q + 1, \dots, q' - 2q : |x_k^{(m)}| > \delta\},$$

and define

$$h(t_k, x_k^{(1)}, \dots, x_k^{(q')}) = \max_{j=0,1,\dots,2q} \left(\sum_{i=m_k}^{m_k+j} x_k^{(i)} \right) - ct_k.$$

Finally, we define

$$h^*(\xi) = \max_{k \in H_\delta(\xi)} h(t_k, x_k^{(1)}, \dots, x_k^{(q')}). \quad (7.11)$$

It follows from Lemma 7.2 that the measure $m^{q'}$ in Theorem 4.1 assigns zero value to the set of discontinuities of h^* .

By the mapping theorem (Lemma A.2), we conclude that for any $\tau > 0$,

$$r_n P(h^*(N_n^{q'}) > \tau) = m_n^{q'}(h^*(N_n^{q'}) > \tau) \rightarrow m^{q'}\{\xi : h^*(\xi) > \tau\}, \quad (7.12)$$

using the fact the right hand side of (7.12) is continuous in $\tau > 0$.

Taking now into account the definition of r_n , the estimate (7.9) and the fact that $n = [u]M$, one obtains from (7.12) that

$$\limsup_{u \rightarrow \infty} \frac{p_n(\delta)}{uP(|Z| > u)} \leq M^{-(\alpha-1)} m^{q'}\{\xi : h^*(\xi) > (1-\varepsilon)M^{-1} - 2\gamma\},.$$

It follows from the form of the limiting measure $m^{q'}$ in the one-dimensional case (see (2.6)) that for any $\tau > 0$,

$$\lim_{\delta \rightarrow 0} m^{q'}\{\xi : h^*(\xi) > \tau\} = \frac{1}{c(\alpha-1)} (\tau^{-(\alpha-1)} - (c+\tau)^{-(\alpha-1)})$$

$$E \left[w \left(\max_{j=0,1,\dots,2q} \sum_{k=-q}^{-q+j} A_{k,k} \right)_+^\alpha + (1-w) \left(\max_{j=0,1,\dots,2q} \sum_{k=-q}^{-q+j} -A_{k,k} \right)_+^\alpha \right],$$

from which we see that

$$\begin{aligned} & \limsup_{q \rightarrow \infty} \lim_{\gamma \rightarrow 0} \limsup_{\delta \rightarrow 0} \limsup_{u \rightarrow \infty} \frac{p_n(\delta)}{uP(|Z| > u)} \\ & \leq M^{-(\alpha-1)} [((1-\varepsilon)M)^{\alpha-1} - (c + ((1-\varepsilon)M^{-1}))^{-(\alpha-1)}] R, \end{aligned}$$

from which (7.10) follows. This proves the upper bound (7.5).

The lower bound requires a similar estimate. Take $\varepsilon > 0$ and let u be sufficiently large that $([u] + 1)/[u] < 1 + \varepsilon$. For (a large) integer $M = 1, 2, \dots$ we have

$$\begin{aligned} \psi(u) & \geq P(\sup_k (S_k - ck) > [u] + 1) \\ & \geq P(\sup_{k \leq [u]M} (S_k - ck) > [u](1 + \varepsilon)) \\ & \geq P(\sup_{k \leq [u]M} (S_k^q - ck) > [u](1 + 2\varepsilon)) \\ & \quad - P(\sup_{k \leq [u]M} \hat{S}_k^q > [u]\varepsilon). \end{aligned}$$

Hence, by Remark 6.2 and assumptions (7.2) and (6.4), it is sufficient to prove that

$$\lim_{M \rightarrow \infty} \lim_{\varepsilon \rightarrow 0} \liminf_{q \rightarrow \infty} \liminf_{u \rightarrow \infty} \frac{P(\sup_{k \leq [u]M} (S_k^q - ck) > [u](1 + 2\varepsilon))}{uP(|Z| > u)} \geq R.$$

Using (7.8) again it is sufficient to consider

$$\frac{P\left(\sup_{k \leq [u]M} n^{-1}(\sum_{i=1}^k X_i I\{n\delta < |X_i| < n/\delta\} - ck) > (1 + 2\varepsilon)/M + \gamma\right)}{uP(|Z| > u)}, \quad (7.13)$$

and the argument from here is the same as in the case of the upper bound. $\square$

Below are the lemmas used in the proof of Theorem 7.1.

Lemma 7.1. *Under the assumptions of Theorem 7.1*

$$\lim_{M \rightarrow \infty} \limsup_{u \rightarrow \infty} \frac{P(\sup_{k > uM} (S_k - ck) > u)}{uP(|Z| > u)} = 0.$$

Proof. We use Theorem 6.1 and Remark 6.1 and 6.2 with $\gamma_n \equiv n$. Choose $\beta > 1$ and $A > 1$ such that

$$E|X_1| < \frac{c(1 - 1/A)}{\beta - 1}, \quad (7.14)$$

and write

$$P\left(\sup_{k > uM} (S_k - ck) > u\right) \leq \sum_{j=1}^{\infty} P\left(S_k > ck \text{ for some } Mu\beta^{j-1} \leq k \leq Mu\beta^j\right).$$

By stationarity of (X_k) , for every $j = 1, 2, \dots$,

$$\begin{aligned} P\left(S_k > ck \text{ for some } Mu\beta^{j-1} \leq k \leq Mu\beta^j\right) &\leq P\left(S_{\lceil Mu\beta^{j-1} \rceil} > \frac{cMu\beta^{j-1}}{A}\right) \\ &+ P\left(S_k > ck + cMu\beta^{j-1}(1 - 1/A) \text{ for some } 0 \leq k \leq Mu(\beta^j - \beta^{j-1})\right). \end{aligned}$$

Using Theorem 6.1 we see that for some positive constant C (that, as usual, may change in the sequel) we have, for u large enough,

$$P\left(S_{\lceil Mu\beta^{j-1} \rceil} > \frac{cMu\beta^{j-1}}{A}\right) \leq CMu\beta^{j-1}P(|Z| > Mu\beta^{j-1})$$

and, by Potter's bound, for M large enough,

$$\frac{P(|Z| > Mu\beta^{j-1})}{P(|Z| > u)} \leq C(M\beta^{j-1})^{-\alpha}.$$

It follows that

$$\limsup_{u \rightarrow \infty} \frac{\sum_{j=1}^{\infty} P\left(S_{\lceil Mu\beta^{j-1} \rceil} > \frac{cMu\beta^{j-1}}{A}\right)}{uP(|Z| > u)} \leq CM^{-(\alpha-1)}.$$

Using the fact that $\alpha > 1$, we let $M \rightarrow \infty$ and see that the above expression converges to zero.

Furthermore, for every $j = 1, 2, \dots$,

$$\begin{aligned} &P\left(S_k > ck + cMu\beta^{j-1}(1 - 1/A) \text{ for some } 0 \leq k \leq Mu(\beta^j - \beta^{j-1})\right) \\ &\leq P\left(\sum_{k=0}^{Mu(\beta^j - \beta^{j-1})} |X_k| > cMu\beta^{j-1}(1 - 1/A)\right) \\ &\leq P\left(\frac{1}{Mu(\beta^j - \beta^{j-1})} \sum_{k=0}^{Mu(\beta^j - \beta^{j-1})} (|X_k| - E|X_1|) > \frac{c(1 - 1/A)}{\beta - 1} - E|X_1|\right). \end{aligned}$$

By the choice of β and A as in (7.14) and the assumption (7.2), we can use the large deviations result (6.8), to conclude that, just as above, for all M large enough,

$$\begin{aligned} & \limsup_{u \rightarrow \infty} \frac{P\left(S_k > ck + cMu\beta^{j-1}(1 - 1/A) \text{ for some } 0 \leq k \leq Mu(\beta^j - \beta^{j-1})\right)}{uP(|Z| > u)} \\ & \leq C(M\beta^{j-1})^{-(\alpha-1)}, \end{aligned}$$

and, as before, these bounds can be summed up over j and, then, one lets $M \rightarrow \infty$ and uses the fact that $\alpha > 1$. This proves the statement of the lemma. $\square$

Lemma 7.2. *Under the assumptions of Theorem 7.1, the measure $m^{q'}$ in Theorem 4.1 does not charge the set of discontinuities of h^* in (7.11).*

Proof. Let Ξ be the subset of $\mathbf{N}_p^{q'}$ consisting of point measures ξ such that

$$\xi([0, 1] \times \{(x_0, \dots, x_{q'}) : |x_i| = \delta, \text{ some } i \in \{0, \dots, q'\}\}) = 0.$$

According to Remark 4.1, the measure $m^{q'}$ is concentrated on the set Ξ , and so it is enough to prove that the functional h^* is continuous at each $\xi \in \Xi$. Let (ξ_n) be a sequence in $\mathbf{N}_p^{q'}$ such that $\xi_n \xrightarrow{v} \xi$. If $H_\delta(\xi) = \emptyset$, then $H_\delta(\xi_n) = \emptyset$ for all n large enough, and so $h^*(\xi_n) = 0 \rightarrow 0 = h^*(\xi)$.

Suppose now that $H_\delta(\xi) \neq \emptyset$. By the definition of the set Ξ we see that for all n large enough (say, $n \geq n_0$), the cardinality of $H_\delta(\xi_n)$ is equal the (finite) cardinality of $H_\delta(\xi)$. Moreover, the vague convergence $\xi_n \xrightarrow{v} \xi$ implies that, for every $n \geq n_0$ there is an enumeration $\{(t_k)^n, (x_k^{(1)})^n, \dots, (x_k^{(q')})^n\}$ of $H_\delta(\xi_n)$ such that for every $k \in H_\delta(\xi)$,

$$((t_k)^n, (x_k^{(1)})^n, \dots, (x_k^{(q')})^n) \rightarrow (t_k, x_k^{(1)}, \dots, x_k^{(q')})$$

componentwise as $n \rightarrow \infty$ (see Resnick (1987)). Therefore, for each such k ,

$$h((t_k)^n, (x_k^{(1)})^n, \dots, (x_k^{(q')})^n) \rightarrow h(t_k, x_k^{(1)}, \dots, x_k^{(q')}),$$

and, since the set $H_\delta(\xi)$ is finite, we conclude that $h^*(\xi_n) \rightarrow h^*(\xi)$, as required. $\square$

Finally, as promised, we provide sufficient conditions for (7.3).

Lemma 7.3. *Assume the hypothesis of Theorem 4.1. If $1 < \alpha \leq 2$, then for every $q \geq 0$ and $\gamma > 0$,*

$$\lim_{\delta \rightarrow 0} \limsup_{n \rightarrow \infty} \frac{P\left(\sup_{k \leq n} \left| \sum_{i=1}^k X_i^q I\{|X_i^q| \leq n\delta\} \right| > n\gamma\right)}{nP(|Z| > n)} = 0.$$

If $\alpha > 2$ the conclusion holds if additionally, for some $\beta > \alpha - 1$ and all $-q \leq j \leq q$,

$$EA_{0,j}^{2\beta} < \infty. \quad (7.15)$$

Proof. Write

$$\begin{aligned} & P\left(\sup_{k \leq n} \left| \sum_{i=1}^k X_i^q I\{|X_i^q| \leq n\delta\} \right| > n\gamma\right) \\ & \leq \sum_{|j| \leq q} P\left(\sup_{k \leq n} \left| \sum_{i=1}^k A_{i,j} Z_{i-j} I\{|X_i^q| \leq n\delta\} \right| > \frac{n\gamma}{2q+1}\right). \end{aligned}$$

We replace below, for simplicity, $\gamma/(2q+1)$ with γ . Since the above sum has a finite number of terms, it is enough to prove the appropriate convergence to zero for each one of the terms separately. For simplicity we consider $j = 0$. Denote

$$B_n = \left\{ \sup_{k \leq n} \left| \sum_{i=1}^k A_{i,0} Z_i I\{|X_i^q| \leq n\delta\} \right| > n\gamma \right\},$$

so that we can write for a small $\rho > 0$

$$\begin{aligned} & P\left(\sup_{k \leq n} \left| \sum_{i=1}^k A_{i,0} Z_i I\{|X_i^q| \leq n\delta\} \right| > n\gamma \right) \\ &= P\left(B_n \cap \{|Z_m| \leq n\rho \text{ for all } m = 1-q, \dots, n+q\} \right) \\ &\quad + P\left(B_n \cap \{|Z_m| > n\rho \text{ for exactly one } m = 1-q, \dots, n+q\} \right) \\ &\quad + P\left(B_n \cap \{|Z_m| > n\rho \text{ for two or more } m = 1-q, \dots, n+q\} \right) \\ &:= p_1(n) + p_2(n) + p_3(n). \end{aligned}$$

Clearly, for every $\rho > 0$,

$$\lim_{n \rightarrow \infty} \frac{p_3(n)}{nP(|Z| > n)} = 0.$$

Next, select $0 < \theta < \delta/(2q+1)$, and introduce the event

$$C_n = \left\{ |A_{i_1,j} Z_{i_1-j}| > n\theta \text{ for some } i_1 = 1, \dots, n, |j| \leq q \right\}.$$

Then

$$\begin{aligned} p_1(n) &\leq P\left(C_n \cap \{|Z_m| \leq n\rho \text{ for all } m = 1-q, \dots, n+q\} \right) \\ &\quad + P\left(B_n \cap C_n^c \cap \{|Z_m| \leq n\rho \text{ for all } m = 1-q, \dots, n+q\} \right) \\ &:= p_{11}(n) + p_{12}(n). \end{aligned}$$

By stationarity,

$$\begin{aligned} p_{11}(n) &\leq (n+2q)P\left(|Z_0| \leq n\rho, \max_{|j| \leq q} |A_{j,j} Z_0| > n\theta \right) \\ &\leq (n+2q)P\left(\max_{|j| \leq q} |A_{j,j}| I\left\{ \max_{|j| \leq q} |A_{j,j}| > \theta/\rho \right\} |Z_0| > n\theta \right). \end{aligned}$$

Therefore,

$$\lim_{n \rightarrow \infty} \frac{p_{11}(n)}{nP(|Z| > n)} = \theta^{-\alpha} E\left[\max_{|j| \leq q} |A_{j,j}|^\alpha I\left\{ \max_{|j| \leq q} |A_{j,j}| > \theta/\rho \right\} \right],$$

and this expression can be made arbitrarily small by selecting ρ small in comparison with θ . Furthermore, the choice of θ guarantees that, on the event C_n^c , one automatically has $|X_i^q| \leq n\delta$ for each $i = 1, \dots, n$. Therefore,

$$p_{12}(n) \leq P\left(\sup_{k \leq n} \left| \sum_{i=1}^k A_{i,0} Z_i I\{|Z_i| \leq n\rho\} \right| > n\gamma \right)$$

Put $m_{n\rho} = EZI\{|Z| \leq n\rho\}$, $\tilde{S}_k = \sum_{i=1}^k A_{i,0}(Z_i I\{|Z_i| \leq n\rho\} - m_{n\rho})$ and take $p > \alpha$ such that $E|A_{0,0}|^p < \infty$. Then

$$\begin{aligned} & P\left(\max_{k \leq n} \left| \sum_{i=1}^k A_{i,0} Z_i I\{|Z_i| \leq n\rho\} \right| > n\gamma\right) \\ & \leq P\left(\max_{k \leq n} |\tilde{S}_k| > n\gamma/2\right) + P\left(\max_{k \leq n} \left| \sum_{i=1}^k A_{i,0} m_{n\rho} \right| > n\gamma/2\right). \end{aligned} \quad (7.16)$$

By Markov's inequality the second term in (7.16) is bounded above by

$$\begin{aligned} P\left(\sum_{i=1}^n |A_{i,0}| > \gamma n/2 |m_{n\rho}|\right) & \leq \left(\frac{n\gamma}{2|m_{n\rho}|}\right)^{-p} E\left(\sum_{i=1}^n |A_{i,0}|\right)^p \\ & \leq \left(\frac{n\gamma}{2|m_{n\rho}|}\right)^{-p} n^{p-1} E \sum_{i=1}^n |A_{i,0}|^p \\ & = \left(\frac{\gamma}{2|m_{n\rho}|}\right)^{-p} E|A_{0,0}|^p. \end{aligned}$$

Since $p > \alpha > 1$, $E|A_{0,0}|^p < \infty$, and $|m_{n\rho}| \sim Cn\rho P(|Z| > n\rho)$ it follows that

$$\limsup_{n \rightarrow \infty} \frac{P\left(\sup_{k \leq n} \left| \sum_{i=1}^k A_{i,0} m_{n\rho} \right| > n\gamma/2\right)}{nP(|Z| > n)} \leq \limsup_{n \rightarrow \infty} C \frac{[n\rho P(|Z| > n\rho)]^p}{nP(|Z| > n)} = 0.$$

To handle the first term in (7.16) we divide into two cases. For $1 < \alpha < 2$ we can take $\alpha < p < 2$ and use the fact that $\tilde{S}_k$ is a martingale with respect to $\mathcal{F}_k = \sigma(\{A_{i,0}\}_{i=1}^n, Z_1, \dots, Z_k)$. Then the Burkholder-Davis-Gundy inequality implies that

$$\begin{aligned} P\left(\max_{k \leq n} |\tilde{S}_k| > n\gamma/2\right) & \leq \frac{C}{(n\gamma)^p} E\left([\tilde{S}]_n^{p/2}\right) \\ & \leq \frac{C}{(n\gamma)^p} E\left(\sum_{i=1}^n |A_{i,0}|^p |Z_i I\{|Z_i| \leq n\rho\} - m_{n\rho}|^p\right) \quad (7.17) \\ & \leq \frac{C}{(n\gamma)^p} n E|A_{0,0}|^p (E|Z|^p I\{|Z| \leq n\rho\} + |m_{n\rho}|^p) \\ & \sim \frac{C}{(n\gamma)^p} n (E|A_{0,0}|^p (n\rho)^p P(|Z| > n\rho) + |m_{n\rho}|^p), \end{aligned}$$

where, in the last step, we use Karamata's theorem. In particular,

$$\lim_{\rho \rightarrow 0} \limsup_{n \rightarrow \infty} \frac{\frac{C}{(n\gamma)^p} n (E|A_{0,0}|^p (n\rho)^p P(|Z| > n\rho) + |m_{n\rho}|^p)}{nP(|Z| > n)} = 0.$$

For $\alpha \geq 2$ a variation of the Fuk-Nagaev inequality (see Petrov (1995) 2.6.6, p. 79) implies

$$\begin{aligned} P\left(\max_{k \leq n} |\tilde{S}_k| > n\gamma/2\right) & = E\left[P\left(\max_{k \leq n} |\tilde{S}_k| > n\gamma/2 \middle| \{A_{i,0}\}\right)\right] \\ & \leq E\left[C_1 (n\gamma)^{-p} \sum_{i=1}^n |A_{i,0}|^p E|Z_i I\{|Z_i| \leq n\rho\} - m_{n\rho}|^p\right] \end{aligned}$$

$$+ E \left[\exp \left\{ -C_2 n^2 \left(\sum_{i=1}^n A_{i,0}^2 \text{Var}(ZI\{|Z| \leq n\rho\}) \right)^{-1} \right\} \right].$$

The first of these terms can be bounded just as (7.17) above. To handle the second term we write $W_n := \sum_{i=1}^n A_{i,0}^2$ and note that, since $\alpha \geq 2$, $\text{Var}(ZI\{|Z| \leq n\rho\})$ is a slowly varying function (this quantity is even bounded when $\text{Var}(Z) < \infty$). Therefore, it is bounded by n^ε for all n sufficiently large, where we choose ε to satisfy $\beta > \frac{\alpha-1}{1-\varepsilon}$. Then it follows that for each $\lambda > 0$,

$$\begin{aligned} E \left[\exp \left\{ -C_2 n^2 \left(W_n \text{Var}(ZI\{|Z| \leq n\rho\}) \right)^{-1} \right\} \right] &\leq E \left[\exp \left\{ -C_3 \frac{n^{2-\varepsilon}}{W_n} \right\} \right] \\ &= E \left[\exp \left\{ -C_3 \frac{n^{2-\varepsilon}}{W_n} \right\} I\{W_n \leq \lambda n^{2-\varepsilon} / \log n\} \right] \\ &\quad + E \left[\exp \left\{ -C_3 \frac{n^{2-\varepsilon}}{W_n} \right\} I\{W_n > \lambda n^{2-\varepsilon} / \log n\} \right] \\ &\leq n^{-C_3 \lambda} + P(W_n > \lambda n^{2-\varepsilon} / \log n). \end{aligned}$$

In particular we may choose $\lambda > (\alpha - 1)/C_3$, which will imply

$$\frac{n^{-C_3 \lambda}}{nP(|Z| > n)} \rightarrow 0,$$

as $n \rightarrow \infty$. We also have, for large n , by the choice of ε ,

$$\begin{aligned} \frac{P(W_n > \lambda n^{2-\varepsilon} / \log n)}{nP(|Z| > n)} &\leq \frac{n^{-\beta(2-\varepsilon)}}{nP(|Z| > n)} E \left(\sum_{i=1}^n A_{i,0}^2 \right)^\beta \\ &\leq \frac{n^{-\beta(1-\varepsilon)}}{nP(|Z| > n)} E A_{0,0}^{2\beta} \rightarrow 0, \end{aligned}$$

by assumption (7.15).

Finally, the term $p_2(n)$ can be treated in the same way as the term $p_1(n)$, if one notices that the single large value of Z_m can contribute to at most $2q + 1$ different X_i . If one chooses δ small enough so that $(2q + 1)\delta < \gamma$, then these terms can be excluded from the sum $\sum_{i=1}^k X_i^q I\{|X_i^q| \leq n\delta\}$ in the first place. Hence the statement of the lemma. $\square$

APPENDIX A. FRAMEWORK

Let $\mathbf{E}$ be a locally compact complete separable metric space and consider the space $\mathbf{N}_p$ of Radon point measures on $\mathbf{E}$. In the main part of the paper $\mathbf{E}$ will be the space $[0, 1] \times (\mathbf{R}^{d(q+1)} \setminus \{0\})$ for some $q \geq 0$ and $d \geq 1$, but here it can be quite arbitrary. Let $(h_i)_{i \geq 1}$ be a countable dense collection of functions in $C_K^+(\mathbf{E})$, the space of nonnegative continuous functions on $\mathbf{E}$ with compact support, such that $\xi_n(h_i) \rightarrow \xi(h_i)$ as $n \rightarrow \infty$ for each $i \geq 1$ implies $\xi_n \xrightarrow{v} \xi$ in $\mathbf{N}_p$. Here $\xrightarrow{v}$ denotes vague convergence. The existence of such a sequence $(h_i)_{i \geq 1}$ is established by Kallenberg (1983) (see also Resnick, 1987, Proposition 3.17). Note also that the functions h_i may be chosen to be Lipschitz with respect to the metric on $\mathbf{E}$. This follows from the fact that the approximating functions in the version of the Urysohn lemma used for the purpose of this construction are already Lipschitz (see Resnick, 1987, Lemma 3.11). In particular, a measure ξ in $\mathbf{N}_p$ is uniquely determined by the

sequence $(\xi(h_i))_{i \geq 1}$. We may and will assume that the collection $(h_i)_{i \geq 1}$ is closed under multiplication by positive rational numbers.

We can identify $\mathbf{N}_p$ with a closed subspace of $[0, \infty)^\infty$ via the mapping $h : \mathbf{N}_p \rightarrow [0, \infty)^\infty$ given by $h(\xi) = (\xi(h_i))_{i \geq 1}$. To see that $h(\mathbf{N}_p)$ is closed in $[0, \infty)^\infty$, let $(x_i^n)_{i \geq 1}$ be a convergent sequence in $h(\mathbf{N}_p)$. That is, $x_i^n \rightarrow x_i$ for each i . Then there exist $\xi_n \in \mathbf{N}_p$ such that $\xi_n(h_i) = x_i^n$ for each $i \geq 1$. The collection $(\xi_n)_{n \geq 1}$ is relatively compact in $\mathbf{N}_p$ because $\sup_n \xi_n(h_i) = \sup_n x_i^n < \infty$ for each i . Hence, there is a convergent subsequence $\xi_{n_k} \rightarrow \xi$. This ξ necessarily satisfies $\xi(h_i) = x_i$ and we conclude that $(x_i)_{i \geq 1} \in h(\mathbf{N}_p)$. Thus, $h(\mathbf{N}_p)$ is closed.

The vague convergence on $\mathbf{N}_p$ can be metrized via a metric d induced from $[0, \infty)^\infty$, defined by

$$d(x, y) = \sum_{i=1}^{\infty} 2^{-i} \frac{|x_i - y_i|}{1 + |x_i - y_i|}, \quad (\text{A.1})$$

for elements $x = (x_i)_{i \geq 1}$ and $y = (y_i)_{i \geq 1}$ in $[0, \infty)^\infty$. This makes $\mathbf{N}_p$ into a complete separable metric space (since it is a closed subspace of the complete separable metric space $[0, \infty)^\infty$). The open ball of radius $r > 0$ in $\mathbf{N}_p$ centered at ξ is denoted $B_{\xi, r}$. Recall that we denote by ξ_0 the null measure in $\mathbf{N}_p$.

We will consider convergence of Radon measures m on the space $\mathbf{N}_p$. The framework considered here is that of Hult and Lindskog (2006) where the underlying space, denoted $\mathbf{S}$ by Hult and Lindskog (2006), is taken to be $\mathbf{N}_p$. The space of Radon measures on $\mathbf{N}_p$ whose restriction to $\mathbf{N}_p \setminus B_{\xi_0, r}$ is finite for each $r > 0$ is denoted $\mathbf{M}_0 = \mathbf{M}_0(\mathbf{N}_p)$. Convergence in $\mathbf{M}_0$ ($m_n \rightarrow m$) is defined as the convergence $m_n(f) \rightarrow m(f)$ for all $f \in C_0(\mathbf{N}_p)$, the space of bounded continuous functions on $\mathbf{N}_p$ that vanishes in a neighborhood of “the origin” ξ_0 .

The typical situation in this paper is that we have a sequence of random point measures (N_n) on $\mathbf{E}$, and we are interested in the convergence

$$m_n(\cdot) := r_n P(N_n \in \cdot) \rightarrow m(\cdot), \quad \text{in } \mathbf{M}_0.$$

A.1. Convergence in $\mathbf{M}_0(\mathbf{N}_p)$. We start with relative compactness criteria. For measures on a general metric space such criteria are given in Theorem 2.7 in Hult and Lindskog (2006).

Theorem A.1. *Let $M \subset \mathbf{M}_0(\mathbf{N}_p)$. M is relatively compact if*

(i) *for each $\varepsilon > 0$,*

$$\sup_{m \in M} m\left(\xi : \sum_{i=1}^{\infty} 2^{-i} \frac{\xi(h_i)}{1 + \xi(h_i)} > \varepsilon\right) < \infty,$$

and

(ii) *for each $h \in C_K^+(\mathbf{E})$ and $\delta > 0$ there exists R such that*

$$\sup_{m \in M} m(\xi : \xi(h) > R) \leq \delta.$$

Proof. We need to check (2.2) and (2.3) of Theorem 2.7 in Hult and Lindskog (2006). Since the metric on $\mathbf{N}_p$ is given by (A.1) (i) immediately implies (2.2) in that reference.

Next note that any set of the form $\prod_{i=1}^{\infty} [0, R_i]$ is a compact subset of $[0, \infty)^\infty$. Hence, $C = \{\xi : \xi(h_i) \leq R_i \text{ for each } i\} \setminus B_{\xi_0, \varepsilon}$ is a compact subset of $\mathbf{N}_p \setminus B_{\xi_0, \varepsilon}$ and

$$\sup_{m \in M} m(\mathbf{N}_p \setminus (B_{\xi_0, \varepsilon} \cup C)) \leq \sup_{m \in M} m(\xi : \xi(h_i) > R_i \text{ some } i \geq 1)$$

$$\leq \sup_{m \in M} \sum_{i=1}^{\infty} m(\xi : \xi(h_i) > R_i).$$

By (ii) we can take R_i such that $\sup_{m \in M} m(\xi : \xi(h_i) > R_i) < 2^{-i}\delta$, which implies (2.3) of Hult and Lindskog (2006). $\square$

To show actual convergence, one needs, in addition to relative compactness, to identify subsequential limits. For this purpose we define for $g_1, g_2 \in C_K^+(\mathbf{E})$, $\varepsilon_1, \varepsilon_2 > 0$, a function $F_{g_1, g_2, \varepsilon_1, \varepsilon_2} : \mathbf{N}_p \rightarrow [0, \infty)$ by

$$F_{g_1, g_2, \varepsilon_1, \varepsilon_2}(\xi) = (1 - \exp\{-(\xi(g_1) - \varepsilon_1)_+\})(1 - \exp\{-(\xi(g_2) - \varepsilon_2)_+\}). \quad (\text{A.2})$$

Note that each $F_{g_1, g_2, \varepsilon_1, \varepsilon_2}$ is a bounded continuous function that vanishes on a neighborhood of the null measure ξ_0 .

Lemma A.1. *Let m_1, m_2 be measures in $\mathbf{M}_0(\mathbf{N}_p)$. If for all Lipschitz functions $g_1, g_2 \in C_K^+(\mathbf{E})$, $\varepsilon_1, \varepsilon_2 > 0$, one has $m_1(F_{g_1, g_2, \varepsilon_1, \varepsilon_2}) = m_2(F_{g_1, g_2, \varepsilon_1, \varepsilon_2})$, then $m_1 = m_2$.*

Proof. We use the assumption with $g_i = h_{j_i}$, $i = 1, 2$. Replacing h_{j_1} by bh_{j_1} and ε_1 by $b\varepsilon_1$ with positive rational b , and let $b \rightarrow \infty$ and $\varepsilon_2 \rightarrow 0$, we obtain

$$\begin{aligned} & \int_{\mathbf{N}_p} I\{\xi(h_{j_1}) \geq \varepsilon_1\} e^{-\xi(h_{j_2})} m_1(d\xi) \\ &= \int_{\mathbf{N}_p} I\{\xi(h_{j_1}) \geq \varepsilon_1\} e^{-\xi(h_{j_2})} m_2(d\xi). \end{aligned} \quad (\text{A.3})$$

Replacing, in (A.3), h_{j_2} by bh_{j_2} as above, and letting $b \rightarrow 0$, we obtain also

$$m_1(I\{\xi(h_{j_1}) \geq \varepsilon_1\}) = m_2(I\{\xi(h_{j_1}) \geq \varepsilon_1\}). \quad (\text{A.4})$$

Since the family $(h_i)_{i \geq 1}$ is dense in $C_K^+(\mathbf{E})$, we conclude that (A.3) holds with h_{j_2} replaced by any function in $C_K^+(\mathbf{E})$. To see that (A.4) and (A.3) imply $m_1 = m_2$ we define, for any $j_1 \geq 1$ and $\varepsilon_1 > 0$, probability measures on $\mathbf{N}_p$ by

$$\begin{aligned} \tilde{m}_1(\cdot) &= \frac{m_1(\cdot \cap \{\xi : \xi(h_{j_1}) \geq \varepsilon_1\})}{m_1(\xi : \xi(h_{j_1}) \geq \varepsilon_1)} \\ \tilde{m}_2(\cdot) &= \frac{m_2(\cdot \cap \{\xi : \xi(h_{j_1}) \geq \varepsilon_1\})}{m_2(\xi : \xi(h_{j_1}) \geq \varepsilon_1)}. \end{aligned}$$

The uniqueness property of the Laplace functionals (see Resnick, 1987, Section 3.2) (A.3) implies that $\tilde{m}_1$ and $\tilde{m}_2$ coincide. Hence m_1 and m_2 coincide on the set $\{\xi(h_j) \geq \varepsilon\}$ for any j and ε . Letting $\varepsilon \rightarrow 0$ we obtain the claim. $\square$

Finally, we are ready to state necessary and sufficient conditions for convergence in $\mathbf{M}_0(\mathbf{N}_p)$.

Theorem A.2. *Let $m, m_1, m_2, \dots$ be measures in $\mathbf{M}_0(\mathbf{N}_p)$. The condition*

$$\lim_{n \rightarrow \infty} m_n(F_{g_1, g_2, \varepsilon_1, \varepsilon_2}) = m(F_{g_1, g_2, \varepsilon_1, \varepsilon_2})$$

for all $g_1, g_2 \in C_K^+(\mathbf{E})$, $\varepsilon_1, \varepsilon_2 > 0$, is necessary and sufficient for the convergence $m_n \rightarrow m$ in $\mathbf{M}_0(\mathbf{N}_p)$. Furthermore, it is sufficient to check the condition only for the Lipschitz functions in $C_K^+(\mathbf{E})$.

Proof. The necessity of the condition is obvious. For the sufficiency we start with checking that the sequence $(m_n)_{n \geq 1}$ is relatively compact in $\mathbf{M}_0(\mathbf{N}_p)$, for which we will check (i) and (ii) in Theorem A.1.

Start by choosing a Lipschitz collection $(h_i)_{i \geq 1}$ as above. Take $\varepsilon > 0$. With $J_\varepsilon = \lceil -\log_2 \varepsilon \rceil + 1$ we have

$$\begin{aligned} m_n \left(\left\{ \xi : \sum_{i=1}^{\infty} 2^{-i} \frac{\xi(h_i)}{1 + \xi(h_i)} \geq \varepsilon \right\} \right) &\leq m_n \left(\left\{ \xi : \sum_{i=1}^{J_\varepsilon} 2^{-i} \frac{\xi(h_i)}{1 + \xi(h_i)} > \frac{\varepsilon}{3} \right\} \right) \\ &\leq \sum_{i=1}^{J_\varepsilon} m_n \left(\left\{ \xi : \frac{\xi(h_i)}{1 + \xi(h_i)} > \frac{\varepsilon}{3J_\varepsilon} \right\} \right) \\ &\leq \sum_{i=1}^{J_\varepsilon} m_n \left(\left\{ \xi : \xi(h_i) > \frac{1}{(3J_\varepsilon/\varepsilon - 1)} \right\} \right). \end{aligned}$$

Note that, for any $h \in C_K^+(\mathbf{E})$ and $R > 0$,

$$m(F_{h,h,R/2,R/2}) = \int (1 - e^{-(\xi(h)-R/2)_+})^2 m(d\xi) \quad (\text{A.5})$$

$$\geq \int (1 - e^{-(\xi(h)-R/2)_+})^2 I\{\xi(h) > R\} m(d\xi) \quad (\text{A.6})$$

$$\geq (1 - e^{-R/2})^2 m(\xi : \xi(h) > R). \quad (\text{A.7})$$

For $\varepsilon > 0$ we choose $R = R(\varepsilon) = \frac{2}{3J_\varepsilon/\varepsilon - 1}$. By the assumption of the proposition there is n_1 such that for all $n \geq n_1$ the bound

$$m_n(F_{h_i,h_i,R/2,R/2}) \leq m(F_{h_i,h_i,R/2,R/2}) + 1$$

holds for each $i = 1, \dots, J_\varepsilon$. It follows from (A.5) that for all such n ,

$$\begin{aligned} m_n \left(\left\{ \xi \in \mathbf{N}_p : \sum_{i=1}^{\infty} 2^{-i} \frac{\xi(h_i)}{1 + \xi(h_i)} \geq \varepsilon \right\} \right) \\ \leq (1 - e^{-R(\varepsilon)})^{-2} \sum_{i=1}^{J_\varepsilon} [m(F_{h_i,h_i,R(\varepsilon)/2,R(\varepsilon)/2}) + 1], \end{aligned}$$

which is finite, establishing (i) in Theorem A.1.

The next step is to check (ii) in Theorem A.1. For $h \in C_K^+(\mathbf{E})$ and $R > 0$ we have by (A.5)

$$\begin{aligned} \limsup_{n \rightarrow \infty} m_n(\{\xi : \xi(h) > R\}) &\leq \limsup_{n \rightarrow \infty} (1 - e^{-R/2})^{-2} m(F_{h,h,R/2,R/2}) \\ &= (1 - e^{-R/2})^{-2} m(F_{h,h,R/2,R/2}). \end{aligned}$$

The latter expression converges to zero as $R \rightarrow \infty$, which implies (ii) in Theorem A.1.

We conclude that (m_n) is relatively compact in $\mathbf{M}_0(\mathbf{N}_p)$.

Since the assumptions of Lemma A.1 are satisfied for any subsequential vague limit point of the sequence (m_n) and the measure m , we conclude that all subsequential vague limit points of the sequence (m_n) coincide with m and, hence, $m_n \rightarrow m$ in $\mathbf{M}_0(\mathbf{N}_p)$. $\square$

A mapping theorem. The general version of the mapping theorem is given in Theorem 2.5 in Hult and Lindskog (2006). Here we will state a useful special case.

Lemma A.2. *Suppose $m_n \rightarrow m$ in $\mathbf{M}_0(\mathbf{N}_p)$ and $f : \mathbf{E} \rightarrow \mathbf{R}^d$ is a measurable function with a bounded support, such that $m(\xi : \xi(\mathcal{D}_f) > 0) = 0$, where $\mathcal{D}_f$ is the set of discontinuities of the function f . Define $T : \mathbf{N}_p \rightarrow \mathbf{R}^d$, by $T(\xi) = \xi(f)$. Then*

$$m_n \circ T^{-1}(\cdot) \rightarrow m \circ T^{-1}(\cdot),$$

in $\mathbf{M}_0(\mathbf{R}^d)$.

Proof. This follows from Theorem 2.5 in Hult and Lindskog (2006) since T is discontinuous on a set of measure m equal to zero, $T(\xi_0) = 0$, and T is continuous at ξ_0 . $\square$
